[CONCURRENT RESOLUTION FEBRUARY 19, 1893.]

Resolved by the House of Representatives (the Senate concurring), That there be printed in quarto form of the annual report of the Chief of the Weather Bureau, with appendixes, 9,000 copies, of which 1,000 copies will be for the use of the Senate, 2,000 copies for the use of the House of Representatives, and 6,000 copies for the use of the Weather Bureau.

CONTENTS.

	Page.
PART I	7
Introduction	9
List of observing stations	11
Table I.—Latitude, longitude, and elevation of first, second, and third order stations	11
Table II.—Changes during 1891 and 1892, stations established, discontinued, etc	16
Description of instruments	19
Instrumental corrections; methods of reduction; resulting accuracy	37
Temperature of the air	37
Pressure	41
Moisture of the air	44
Winds	45
Sunshine and cloudiness	46
Evaporation	47
Precipitation	47
PART II.—Monthly averages for each hour of the day at 28 stations	49
Pressure, 1891	50
Pressure, 1892	64
Temperature, 1891	78
Temperature, 1892	92
Wind, 1891	108
Wind, 1892	124
PART III.—Monthly and annual meteorological summaries for Weather Bureau stations	141
1891	142
1892	222
PART IV.—Monthly and annual mean temperature, annual extremes of temperature, and dates of first and last killing frost, 1891–'92	305
1891	307
1892	336
PART V.—Monthly and annual precipitation at all stations	367
1891	369
1892	401
PART VI.—Miscellaneous meteorological tables and reports	435
Normal pressure (monthly)	438
Normal temperature (monthly)	442
Normal precipitation (monthly)	444
Snowfall, 1891–'92	447
Sunshine, 1891	457
Sunshine, 1892	469
River stages	483
Local storms in the United States during 1890, 1891, and 1892	505
Casualties due to lightning	510
High and low areas of barometric pressure, 1891–'92	511
A balloon ascension	517
Report on the relations of solar magnetism to terrestrial magnetism and meteorology	519
Report on condensation of atmospheric moisture	526

INTRODUCTION.
LIST OF OBSERVING STATIONS.
DESCRIPTION OF INSTRUMENTS.
INSTRUMENTAL CORRECTIONS—METHODS OF REDUCTION; RESULTING ACCURACY.

REPORT OF THE CHIEF OF THE WEATHER BUREAU.

INTRODUCTION.

There will be found in this, the initial volume of meteorological data published by the Weather Bureau, the results of observations made during 1891 and 1892—continuing the series heretofore published by the War Department—and other climatological tables of general interest and importance in connection with the current work of the Bureau.

A word of explanation in regard to the tables selected for publication may be necessary. It has been impossible to follow the plan originally intended, owing to a variety of causes, chief of which was the absolute necessity of crowding two years' observations into the space intended for one. In condensing the work the detailed hourly and twice daily observations have been omitted; it should be remembered, however, that detailed observations from about 150 stations are regularly published on the daily weather maps, and that the latter can be obtained by anyone desiring them on conditions made known on application. As regards the character of the data given in the tables and the form in which the tables are cast, I would say that it has been the endeavor to follow, as closely as the varied requirements of this Bureau will permit, the plan recommended by the International Meteorological Congress for adoption by meteorological services the world over.

In addition to the results of observations for 1891 and 1892, tables of monthly and annual normal pressure, temperature, and precipitation will be found in Part VI; the conditions upon which this volume is printed, however, will not admit of presenting a series of suitable charts to further illustrate the geographical distribution of these and other important meteorological elements.

Attention is directed to the description of the instrumental equipment of observing stations drawn up by Prof. Charles F. Marvin, and also to the report of Prof. Cleveland Abbe on the instrumental corrections, methods of reduction, and the probable resulting accuracy of the observations, and the means which appear in this volume. Both reports supply much valuable information not heretofore accessible to the general public. In another year it may be possible to furnish a brief account of the local topography of each station in so far as it may affect the value of the observations.

The meteorological data published by the Weather Service of the United States while under military control—1870 to 1890—will be found in the stated reports of the Chief Signal Officer and the Monthly Weather Reviews published by the War Department.

The publications of the Weather Bureau, other than the present volume, containing meteorological data are the Monthly Weather Review and the Weekly Weather Crop Bulletin, both of which are more or less fully described in the reports of the honorable Secretary of Agriculture for 1891 and 1892.

The special publications of the Weather Bureau to December 31, 1892, are as follows:

BULLETINS OF THE WEATHER BUREAU.

No. 1.—Notes on the climate and meteorology of Death Valley, California, by Mark W. Harrington, Chief of the Weather Bureau. June, 1892. (Octavo) 50 pp.

No. 2.—Notes on a new method for the discussion of magnetic observations, by Frank H. Bigelow, Professor of Meteorology. July, 1892. (Octavo) 41 pp.

No. 3.—A report on the relations of soil to climate, by E. W. Hilgard, Professor of Agriculture and Agricultural Chemistry, University of California. July, 1892. (Octavo) 59 pp.

No. 4.—Some physical properties of soils in their relation to moisture and crop distribution, by Milton Whitney, Professor of Geology and Soil Physics, Maryland Agricultural College; Physicist, Maryland Agricultural Experiment Station; Fellow by Courtesy, Johns Hopkins University. August, 1892. (Octavo) 90 pp.

No. 5.—Observations and experiments on the fluctuations in the level and rate of movement of ground-water on the Wisconsin Agricultural Experiment Station Farm and at Whitewater, Wis., by Franklin H. King, Professor of Agricultural Physics, University of Wisconsin; Physicist, Wisconsin Agricultural Experiment Station. December, 1892. (Octavo) 75 pp.

No. 6.—The diurnal variation of barometric pressure, by Frank N. Cole, PH. D., Assistant Professor of Mathematics, University of Michigan. December, 1892. (Octavo) 32 pp.

MARK W. HARRINGTON,
Chief of Weather Bureau.

WASHINGTON, D. C., *May 20, 1893.*

LIST OF OBSERVING STATIONS.

The following table contains the geographical coördinates of the several stations whose summaries are published in Part III, the height of the barometer cistern above mean sea level, and of other instruments above ground, the difference between local and standard time, and the date on which observations began. The standard time used by the Weather Bureau in all of its synchronous work is that of the seventy-fifth meridian (Eastern time), which standard is always understood unless otherwise expressed.

The elevations given are for January 1, 1891, except at stations established subsequent to that date. (See Table II.) Elevations followed by the letter "B" have been determined by the barometer; all others are the results of precise levels. Changes made during 1891 and 1892 are given in the second or third set of figures, as the case may be.

The significance of the bold face letter or letters following the name of station is as follows:

P=continuous records of pressure (on December 31, 1892);
T=continuous records of temperature (on December 31, 1892);
W=continuous records of wind (direction and velocity) (on December 31,1892);
V=continuous records of wind (velocity only) (on December 31, 1892);
R=continuous records of rainfall (on December 31, 1892);
S=continuous records of sunshine (on December 31, 1892).

Stations having no letter make an observation of temperature, precipitation, direction of the wind, and the state of the weather daily at 8 p. m.

DESCRIPTION OF INSTRUMENTS.

By Prof. C. F. MARVIN.

The instrumental equipment of the principal stations of the Weather Bureau is set forth in the accompanying lists:

Equipment of instruments, etc., at second-order stations:
Two anemometers, Robinson pattern, 4-inch cups, arms 6.72 inches.
One anemometer register, single.
Two mercurial barometers (Fortin ¼-inch tube).
One glass barometer case.
One set maximum and minimum thermometers, with mountings.
One extra set maximum and minimum thermometers.
Two sets wet and dry bulb mercurial thermometers.
One whirling apparatus for wet and dry bulb thermometers.
One standard instrument shelter, about 3 feet cube, with supports.
One standard anemoscope, tail 3 feet by 10 inches.
One iron anemoscope support, with anti-friction mountings, etc.
One iron anemometer support, or parts to combine with support for anemoscope.
One 8-inch brass rain gauge, with support and measuring sticks.
One 8-inch galvanized iron snow gauge, with support. Batteries, wire, etc.
Additional instruments at first-order stations:
One double or triple register, recording wind and rain (Weather Bureau pattern).
One set electrical contacts, and box, for anemoscope.
One sunshine recorder (Jordan—Weather Bureau pattern).
One electrically recording rain gauge (Marvin's pattern, 1888).
One aneroid barograph (Richard Bros.).
One thermograph (Richard Bros.).
One thermograph recording electrically at a distance (Richard Bros.).

In the case of the equipment of stations of the second order no variation or departure from the above list of instruments occurs, but owing to limited supplies and other circumstances the first-order stations do not in every case have all the additional instruments cited. Thus, only a portion are supplied with sunshine recorders and the electrically recording rain-gauge, and only seven electrically recording thermographs are in use.

On the other hand, about 20 stations of the second order have either thermograph or barograph, or both, in use.

Again, the station at Washington has a still more complete equipment than the regular first-order stations, and the instruments in many respects are of much superior pattern, as will be seen from the descriptions following.

DESCRIPTION OF INSTRUMENTS.

Anemometer.—The standard anemometer used by this Bureau since November, 1870, is of the Robinson pattern, as shown in Fig. 1. In point of portability and facility of exposure, in point of durability, with little attention and convenience of access to all parts, in point of its sensitiveness to light winds (actuated by winds of one-half mile per hour, 0.2 meter per second) and ability to withstand violent storms, indicating sometimes velocities of from 80 to 100 miles per hour, 36 to 45 meters per second, the Weather Bureau anemometer possesses advantages over other forms. Its dimensions and construction are as follows: Diameter of spun brass or alumi-

num cups, 4 inches. Length of arms from axis to cup centers, 6.72 inches. Revolution of cups per nominal mile of wind movement, 500. Dials graduated to miles and tenths. The maximum count in one complete cycle of dial movements, 990 miles. Distance of dials below the cups, 10.5 inches. Weight of cups and spindle, brass, 16 ounces (453 grammes); aluminum, 10.2 ounces (289 grammes); weight of spindle, 2 ounces (57 grammes).

The construction of the dial and registering mechanisms, the insulated binding post, and the oil cup construction of the bottom bearing is shown in Figs. 2 and 3. The outer dial makes one

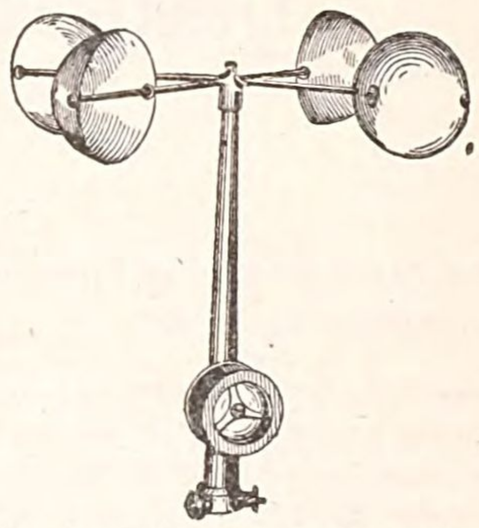

FIG. 1.—Robinson's cup anemometer.

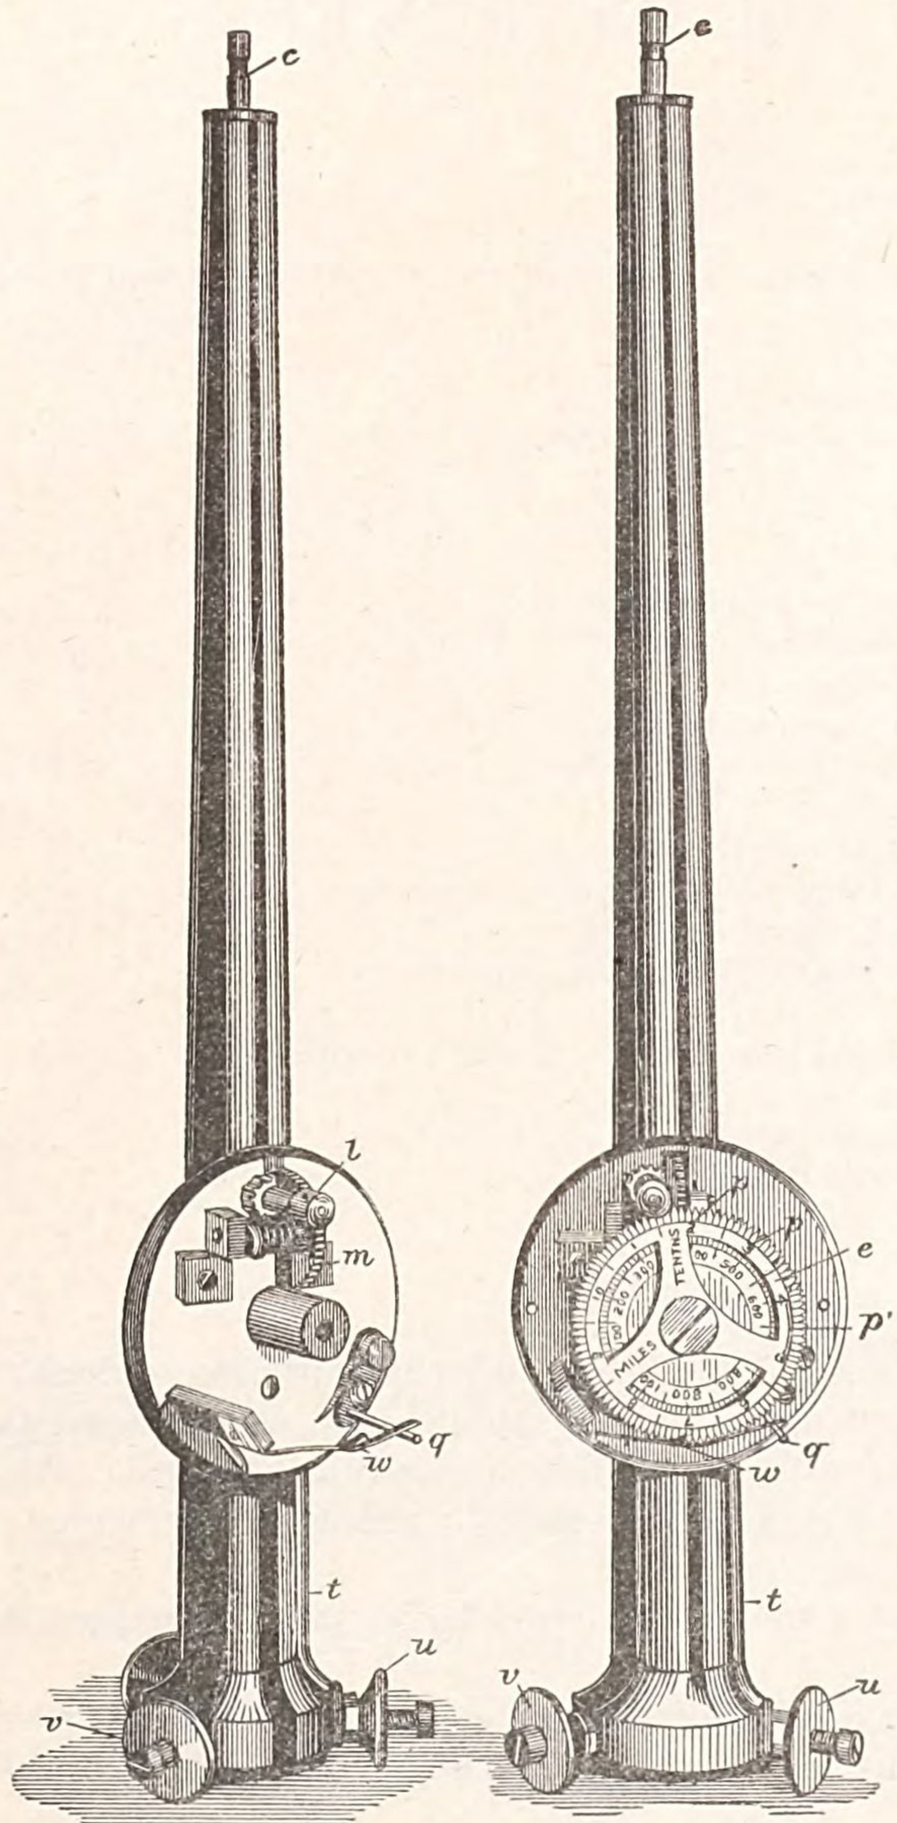

FIG. 2.—Standard anemometer, U. S. Weather Bureau.

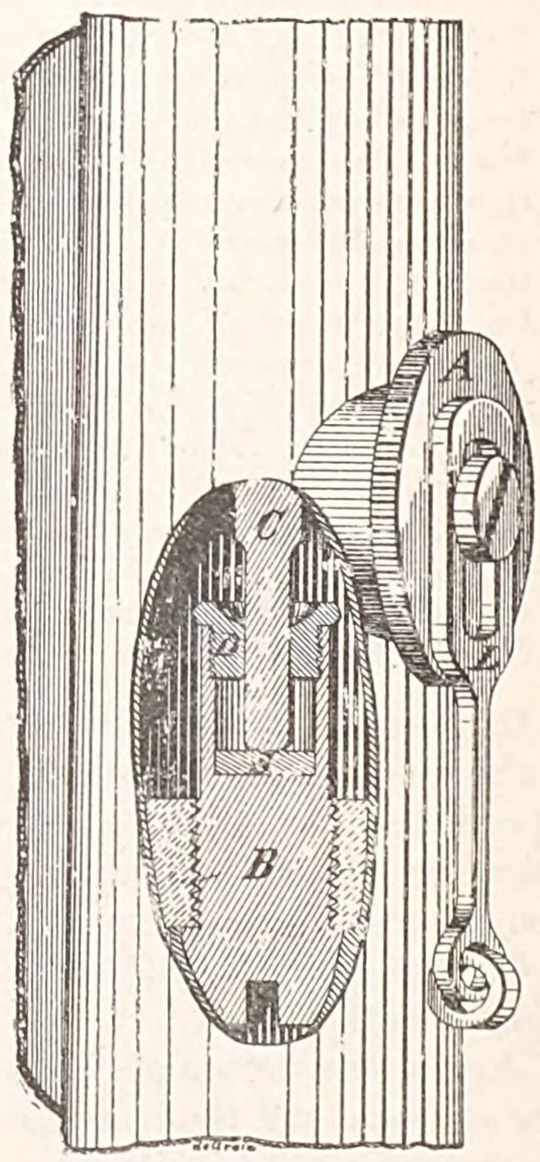

FIG. 3.—Anemometer bearings.

complete revolution for 5,000 revolutions of the spindle; that is, for 10 miles of wind movement. Each mile is registered electrically by a system of ten dial pins, which, as they pass, deflect a spring and momentarily close an electric circuit. The pins at the points marked 4—5 Fig. 2 are joined as shown, the effect of which is to prolong the closure of the circuit until both pins have passed. The resulting record shows a peculiar mark for each 10 miles of wind movement. This mark affords a very satisfactory check upon the accidental omission of a mile mark or so and greatly facilitates counting up the records.

The construction of the oil cup and pivot bearing is shown in Fig. 3. Access is conveniently provided to these parts by means of a comparatively large opening in the case, closed by the cap *A*. This is held in place only by gentle spring friction, but is prevented from being lost by the link, *L*, which secures it to the case. The oil-cup bearing for the spindle *C* is readily understood.

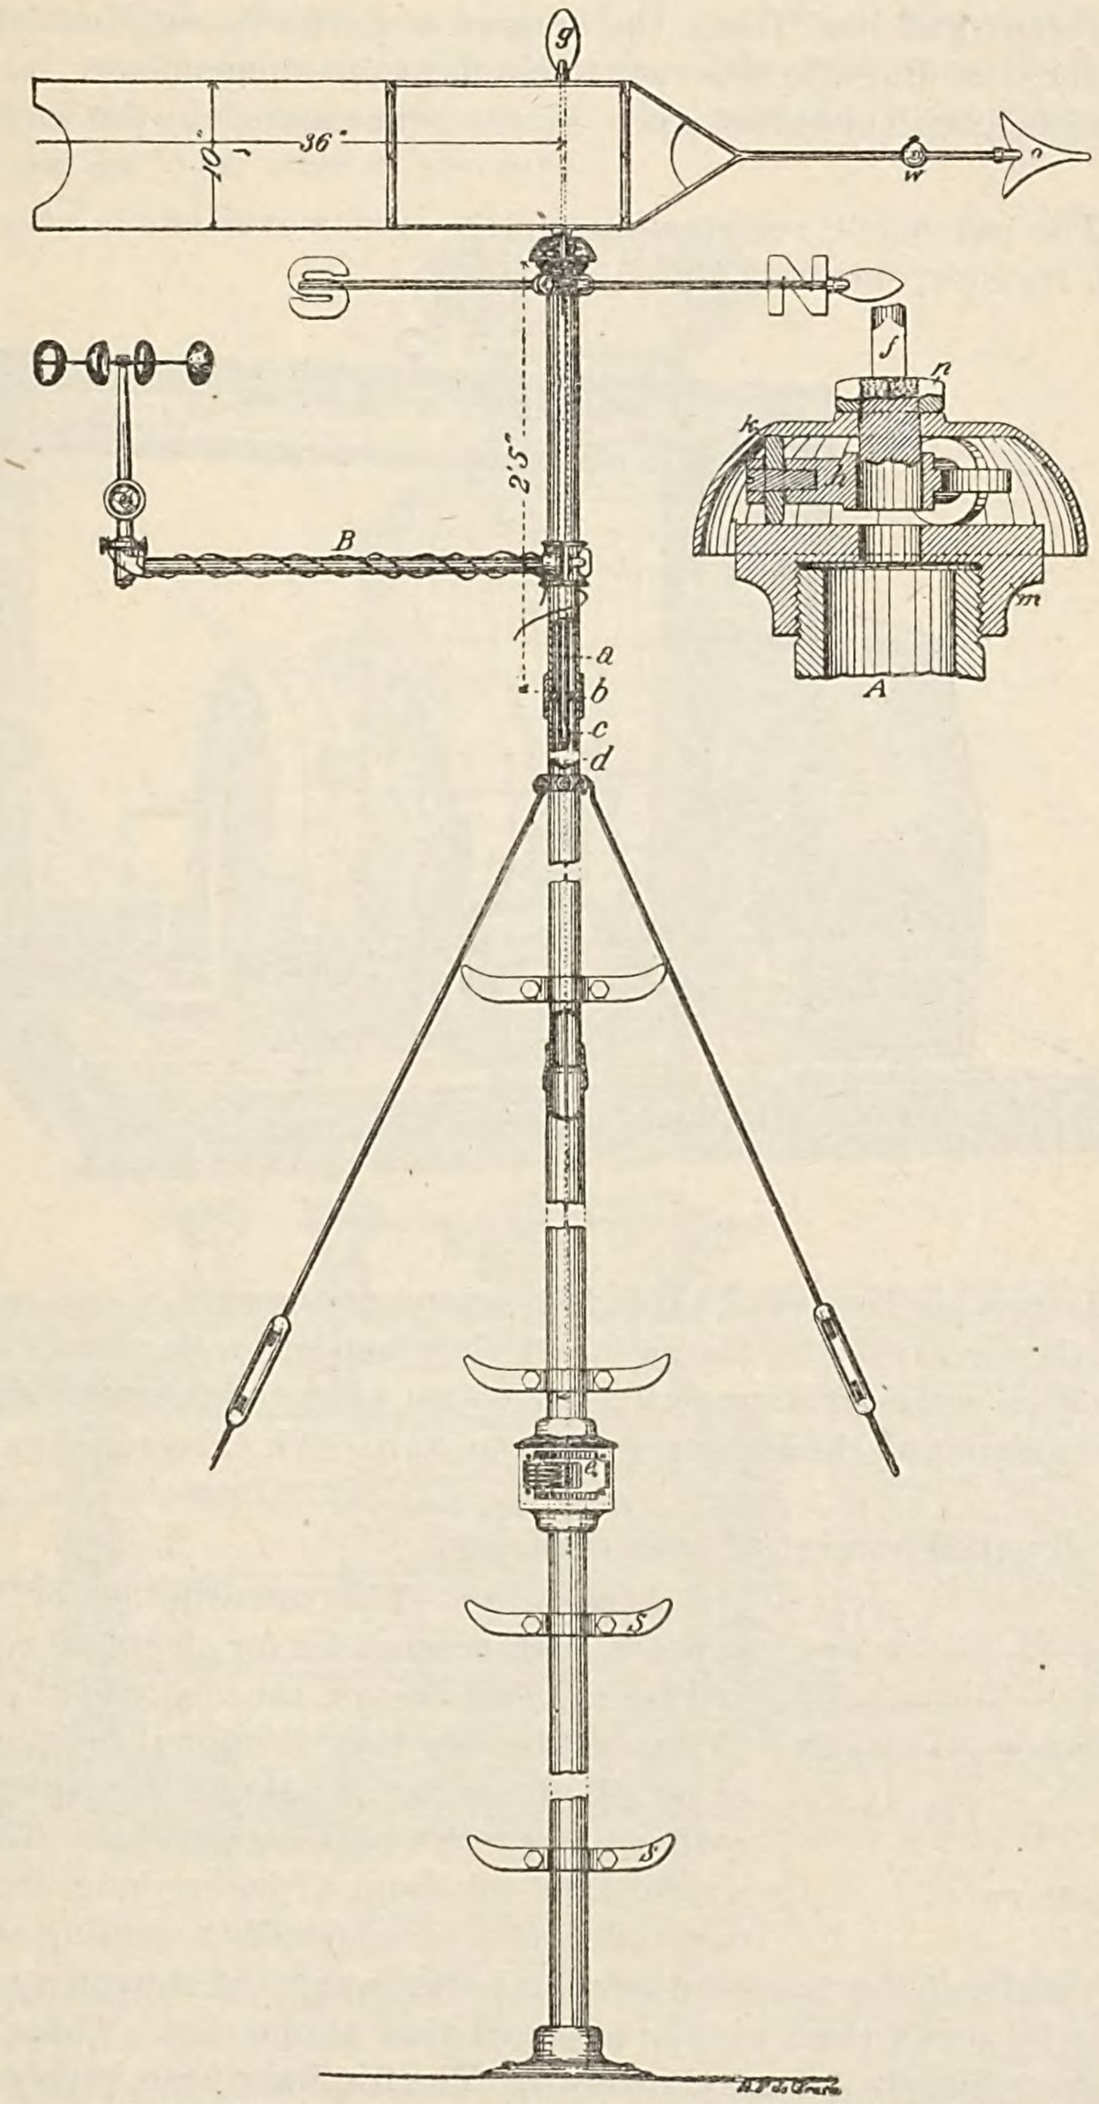

FIG. 4.—U. S. Weather Bureau combined wind vane and anemometer support.

S is a small, flat disc of glass-hard and highly polished steel. *C* is also hardened at the end and highly polished. The annular space between *S* and *D* is filled with the best quality of clock oil, selected with a view to its low freezing point.

Anemometer support.—The anemometer is generally exposed at a height of about 16 to 20 feet above the roof of the office building, the support being made up of 1½ and 2 inch iron pipe, braced

with suitable guy rods. Access to the anemometer was had in the earlier days by causing the top portion of the support to telescope into the bottom portion, thus lowering the instrument to a convenient point. Such a support is not sufficiently rigid and manageable. The Maring support, also formerly used, operated somewhat like the old well sweep to lower the anemometer to the roof. In the more recent and best forms the support is perfectly rigid and fitted with iron foot rests forming a ladder, enabling the observer to climb to the anemometer.

The anemometer is often supported upon a cross arm secured to the wind-vane support, see *B*, Fig. *4*.

Registration.—The automatic registration of the wind movement is effected by means of a special chronograph register, shown in Fig. 5.

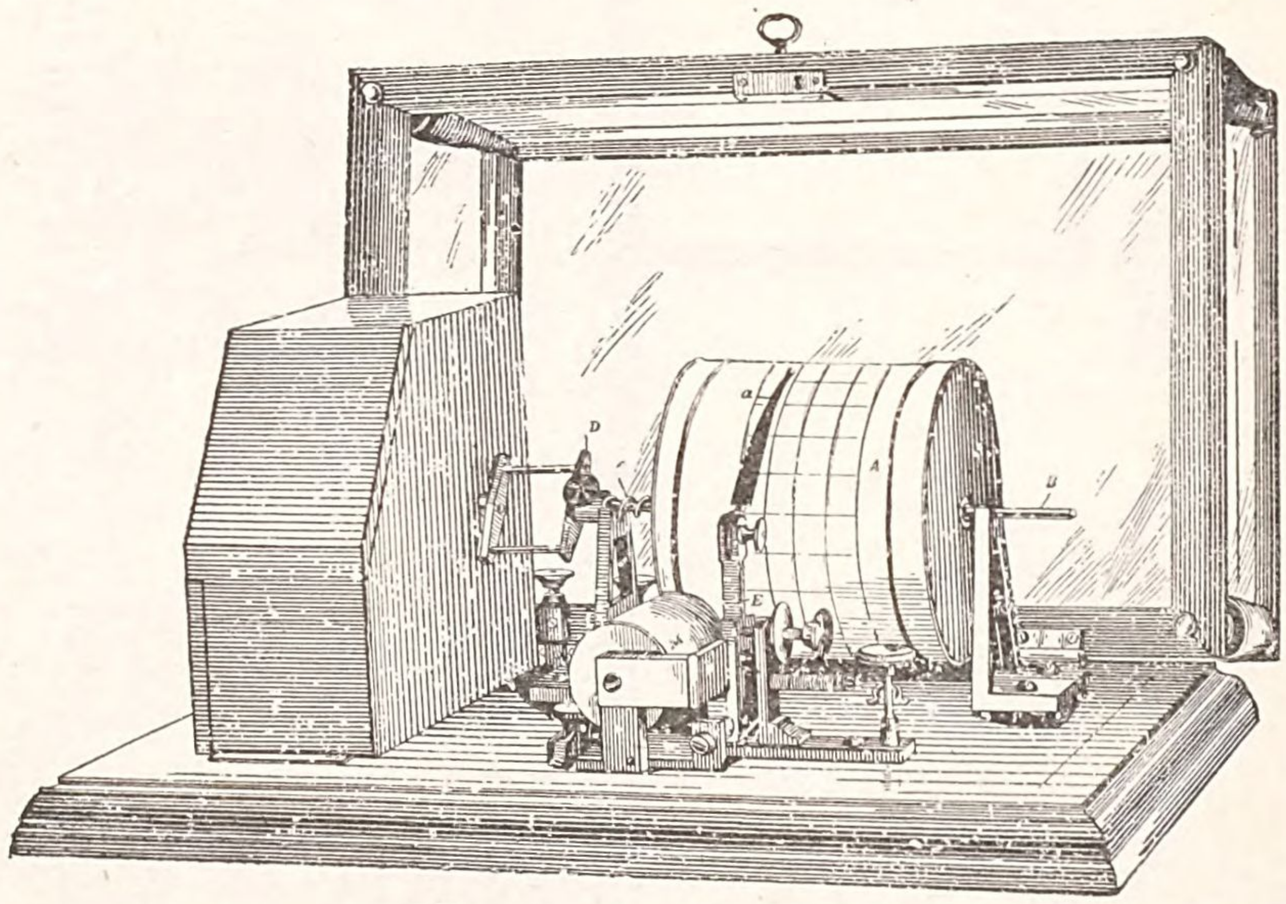

FIG. 5.—Single anemometer register.

The cylinder *A* carrying its record sheet is revolved at the rate of one revolution in 6 hours, moving endwise at the same time by the action of the steep screw or worm *C* on the axis *B*. The mile and ten-mile marks corresponding to the movement of the anemometer dials are made by the action of the electro-magnet on the armature and pen, at *a*. An enlarged view of the pen is shown in Fig. 6.

The sheets are changed and set at noon each day.

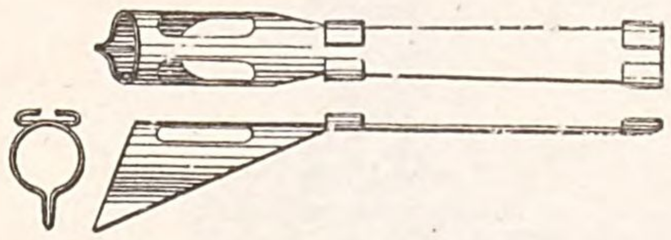

FIG. 6.—Register pen.

Anemoscope.—The construction of the wind vane and support, with accessories for electrical registration, is shown in Fig. 4. This design, especially of the moving parts, aims to insure the very least frictional resistance, even with little or no oil, and as far as possible to require no special skill or care in the erection of the apparatus. The axis of the vane is a solid iron rod about 42 inches long, tapered at the top and squared to fit a corresponding opening edgewise through the vane. The entire weight of the vane and moving parts is supported upon a system of three hard brass rollers or wheels, partly shown in the enlarged view at one side. These wheels are mounted in a carriage, *h*, slipping loosely around the axis, *f*. The friction wheels revolve between the under surface of the bell cover, *n*, and the cap, *m*. The former, being only loosely centered and not held rigidly on the axis, *f*, is free to adjust itself perfectly to the plane of the three anti-friction wheels, notwithstanding irregularities in angles and alignments that unavoidably occur in setting up such apparatus. The lower end of the axis, *f*, passes loosely through a diaphragm or bearing of brass inserted at *b*, within the coupling of the pipe. This construction furnishes strong and durable bearings remarkably free from friction.

The tail of the vane is made of two thin wooden boards of dimensions shown, and which are spread about 9 inches apart at the end.

The support is of wrought-iron pipe 2 inches inside diameter at the bottom and 1½ inches at the top portions. The total height is rarely less than 18 feet, sometimes 24 or more. A set of three iron guy rods, which can be strained taut by turn-buckles, renders the support perfectly rigid.

Iron foot steps, as shown at *s*, *s*, afford access to the vane or to the anemometer when the latter is supported on the cross-arm as shown. In this case the cups of the anemometer are from 18 to 24 inches below the lower edge of the vane.

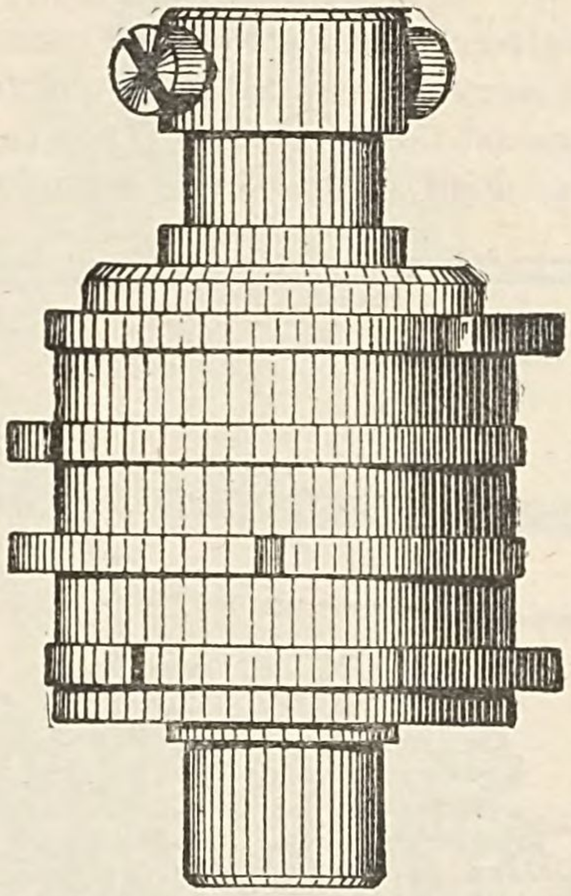

FIG. 7.—Cam collars for electrical contacts.

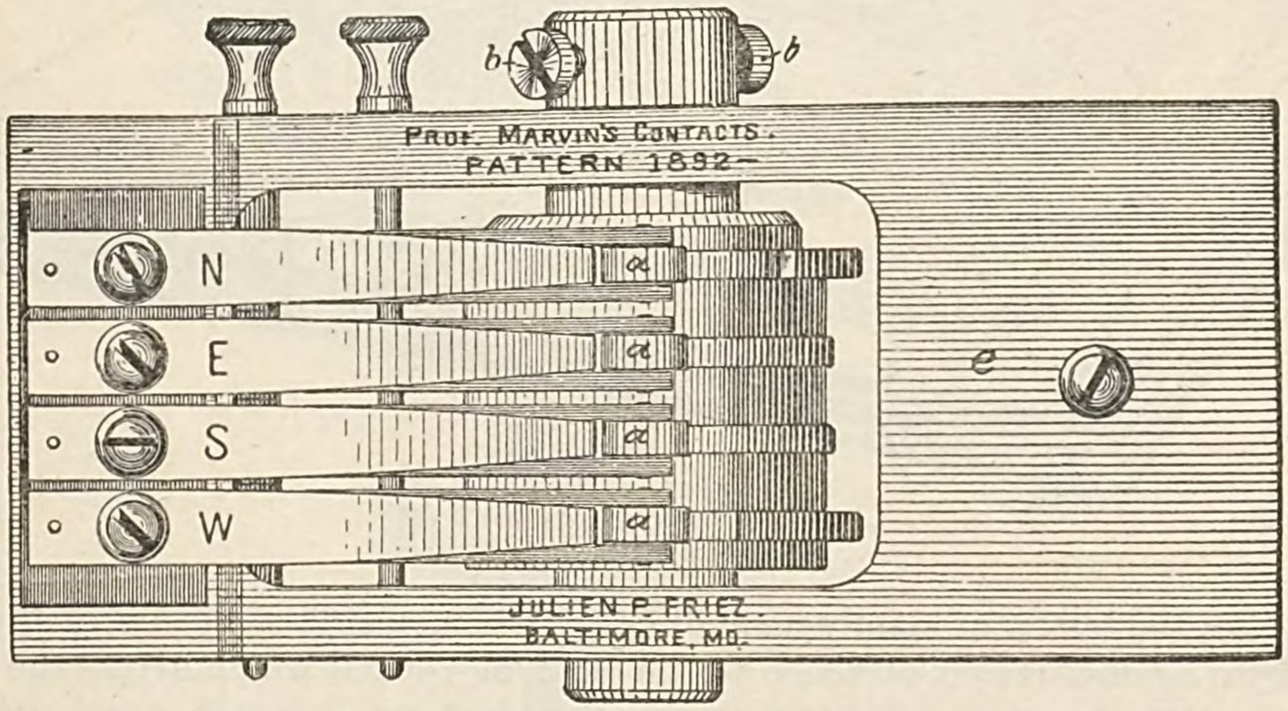

FIG. 8.—Electrical contacts complete.

Electrical registration.—For purposes of electrical registration of the wind direction a contact box is inserted at a convenient height above the base of the support, as seen in Figure 4. The axis of the vane is extended by screwing into the pipe coupling at *d*, Fig. 4, a length of ⅛-inch gas pipe sufficient to pass through the contact box. This pipe is aligned as perfectly as possible, but if not perfectly straight it is so slender and flexible as to readily transmit the motion of the vane with little frictional resistance.

The contact mechanisms are shown separately in Figs. 7 and 8.

The ⅛-inch pipe passes through the center of the cam collars, which are firmly clamped to it by suitable screws. The acting surfaces of the four exactly similar cams embrace just three-

eighths of a circumference, the surfaces of two adjacent cams overlapping just one-eighth of a circumference. These cams, acting upon the rollers *a*, *a*, *a*, *a*, of the contact levers and insulated springs *N*, *E*, *S*, *W*, cause always one, sometimes two of the levers to be in contact each with its corresponding insulated spring, thus indicating, within one-eighth of the circumference, the azimuth of the vane.

The automatic record of these directions, together with record of other elements, is obtained by use of the meteorograph, which is shown in Fig. 9. The chronograph cylinder, *A*, makes 4 revolutions each 24 hours, shifting endwise about three-eighths of an inch per revolution. Four electro-magnets, partly seen, at *W*, *W*, are joined separately, each to each, to the four-contact springs, *N*, *E*, *S*, *W*, of the contact mechanism of the wind vane. The armatures of these magnets are provided with projecting arms carrying rounded points, or letters, on the outer ends. A small swinging ink-pad rests lightly against these points. When the magnet is momentarily actuated by an electric current the letter, or point, of the corresponding arm is impressed against the record

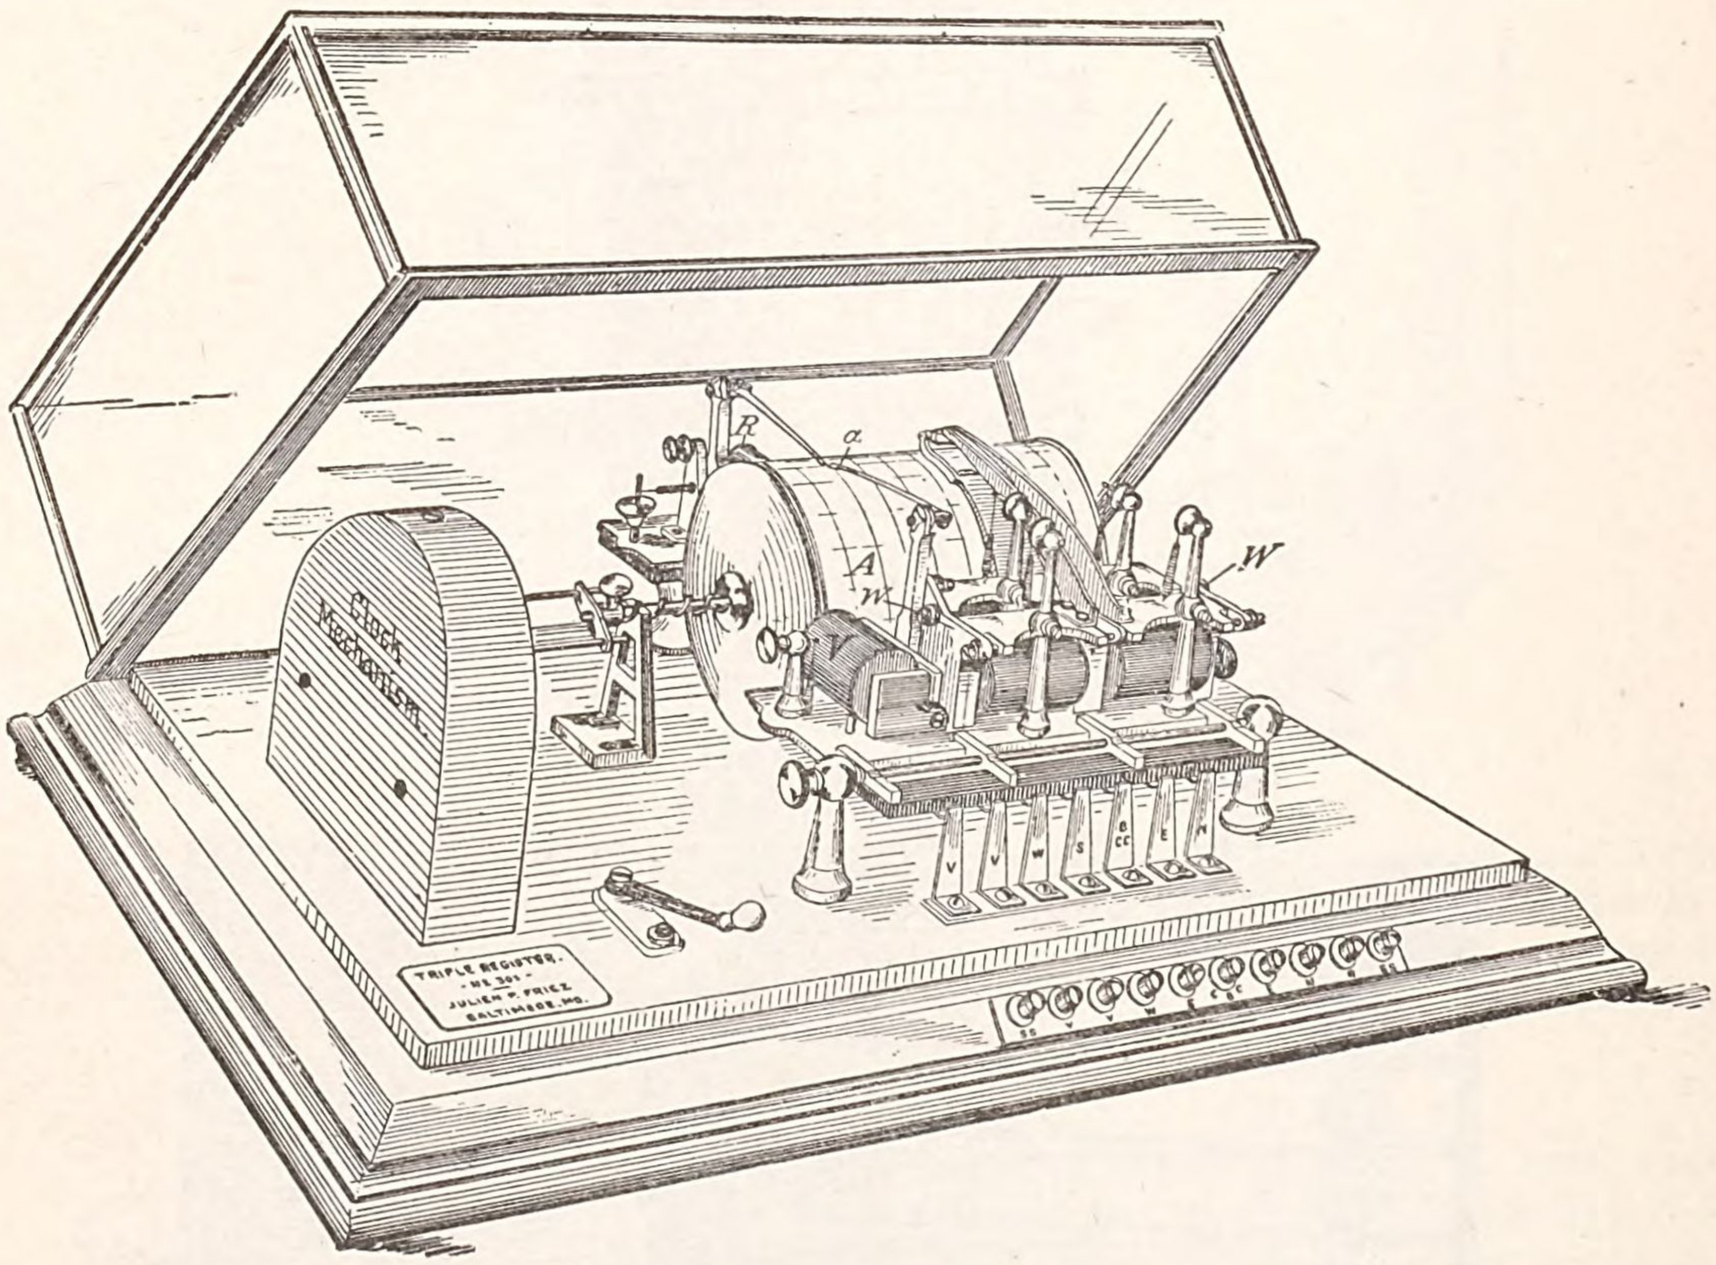

FIG. 9.—Improved triple register.

sheet, imprinting the letter, or simply a small dot. The momentary closure of the electric circuit is produced by a contact-maker attached to the clock movement which drives the record cylinder. Formerly this mechanism closed the circuit only once each five minutes, but in the latter forms of the instrument a one-minute contact-circuit-maker has been introduced, chiefly because of the advantage offered in securing a shorter closure and a simpler construction.

The registration of the wind velocity is effected by means of the electro-magnet, *V*, in the manner already described for the anemometer.

Rainfall.—An electro-magnet, *R*, on the rear side of the cylinder, is connected with the recording rain gauge described below, and produces on the sheet a record of rainfall near to, and in a trace parallel with, the wind-velocity record.

Barometers.—The mercurial barometers are of the usual Fortin cistern type, except that, in later years, many barometers have been fitted with a metal cistern of the piston type, devised by Mr. Chas. B. Tuch, of the Instrument Room. This is shown in section in Fig. 10, from which the construction will be readily understood. The tubes of all barometers are from one-fourth to five-

sixteenths of an inch in diameter inside, and are, with rare exceptions, filled at this office. The boiling process is used in this operation, the mercury being purified by distillation in vacuo. The verniers read to one one-hundredth of an inch in some instruments, and in others to one five-hundredth part of an inch.

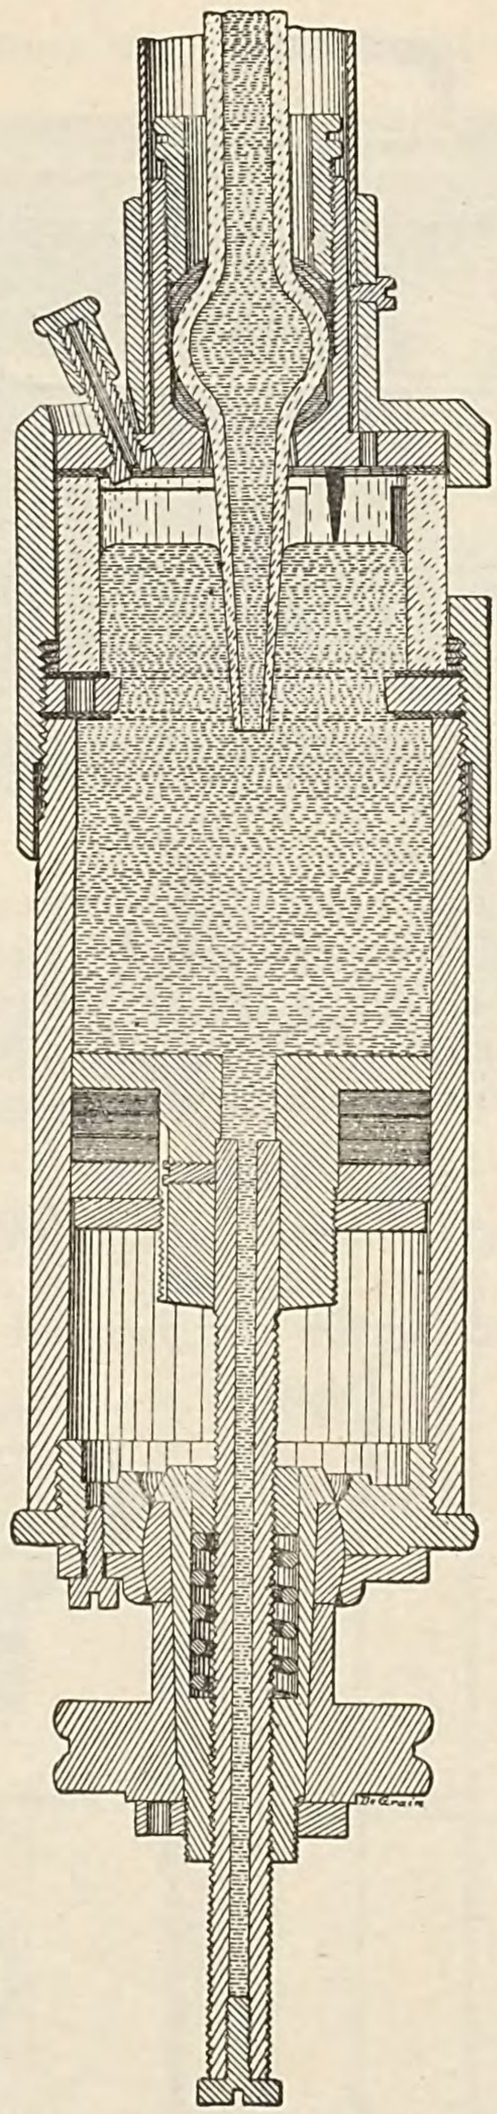

FIG. 10.—Section of Tuch's barometer cistern.

For the better protection from dust, temperature changes, etc., the barometers are suspended in a box. The cistern of each barometer is encircled very loosely by a ring and the top support is adjustable, so that the barometer may be centered within the ring and thus secure free suspension and verticality, affording at the same time means for steadying the cistern against the ring for setting without sensible error in verticality.

Barograph.—The only form of barograph in use at the regular stations, Washington excepted,

is the aneroid barograph of the construction of Richard Bros. This is shown in Fig. 11, and consists essentially of a system of corrugated aneroid cells communicating their motion by means of magnifying levers to the pen, tracing its successive positions upon the sheet of the recording cylinder, as shown. The sheet contains the records for seven days; the vertical scale being full

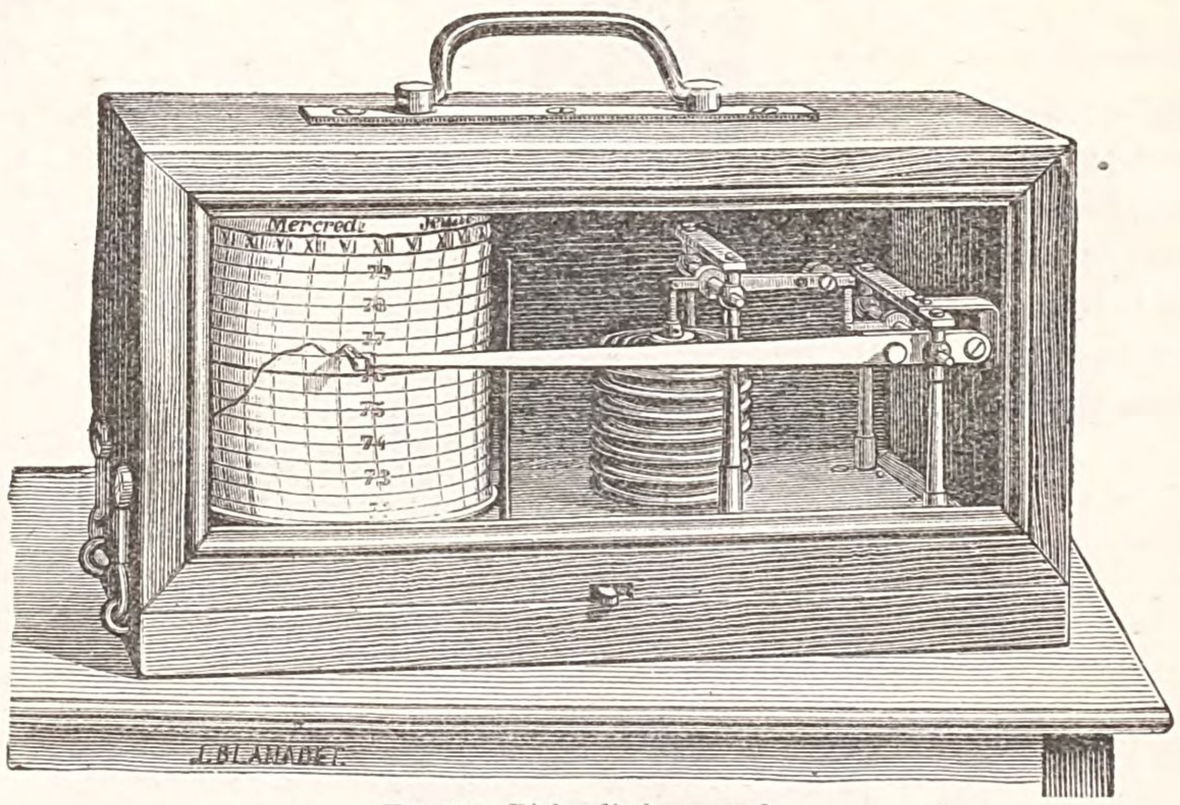

FIG. 11.—Richard's barograph.

size, that is, 1 inch on the sheet represents 1 inch of barometric pressure. The finest rulings represent 0.05 inch of pressure, and the time scale is ruled for intervals of two hours. The limit of accuracy of readings is about 10 to 15 minutes in time and from 0.02 to 0.03 inch of pressure.

Corrections.—The readings at 8 a. m and 8 p. m., as taken from the sheet, are compared with the eye readings of the standard mercurial barometer, and, when necessary, the barograph readings

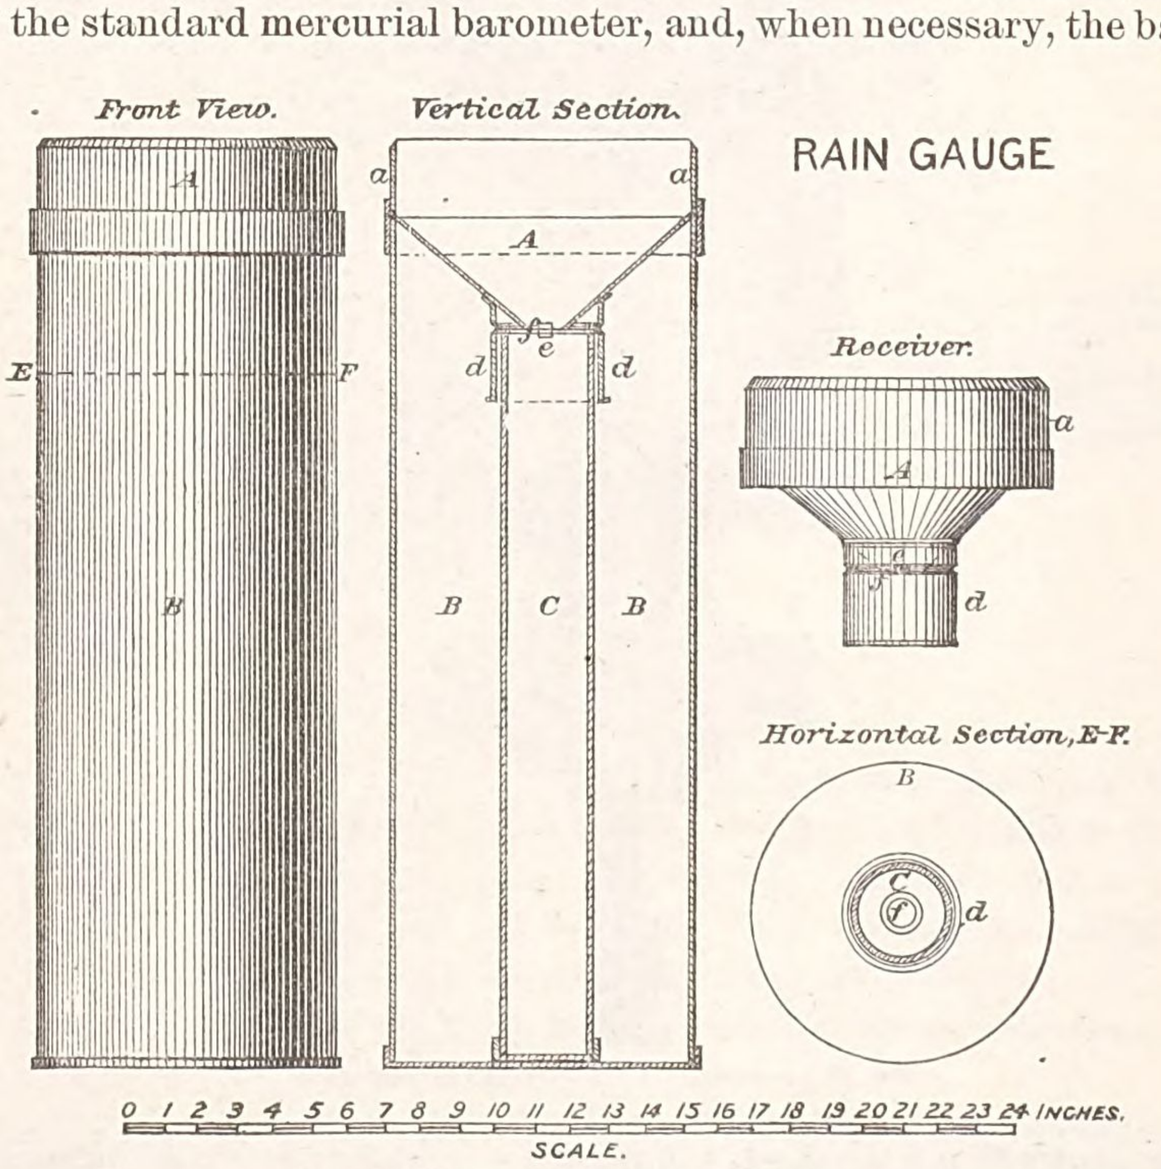

FIG. 12.—Rain and snow gauge, ordinary.

for each hour, as obtained from the sheet, are corrected by interpolated values, if need be, so as to conform throughout to the mercurial barometers.

Rain and Snow Gauges.—These instruments are of very simple construction and will be fully understood from the drawing, Fig. 12.

The receiver of the rain gauge is made of drawn brass tubing, 8 inches in diameter and beveled to a sharp edge at the top. This empties into the measuring tube, also of drawn-brass tubing, having one-tenth the sectional area, and 20 inches high. The measuring sticks are made of cedar, of sectional area generally little less than one one-hundredth that of the measuring tube. The large

Rain Gauge and Support.

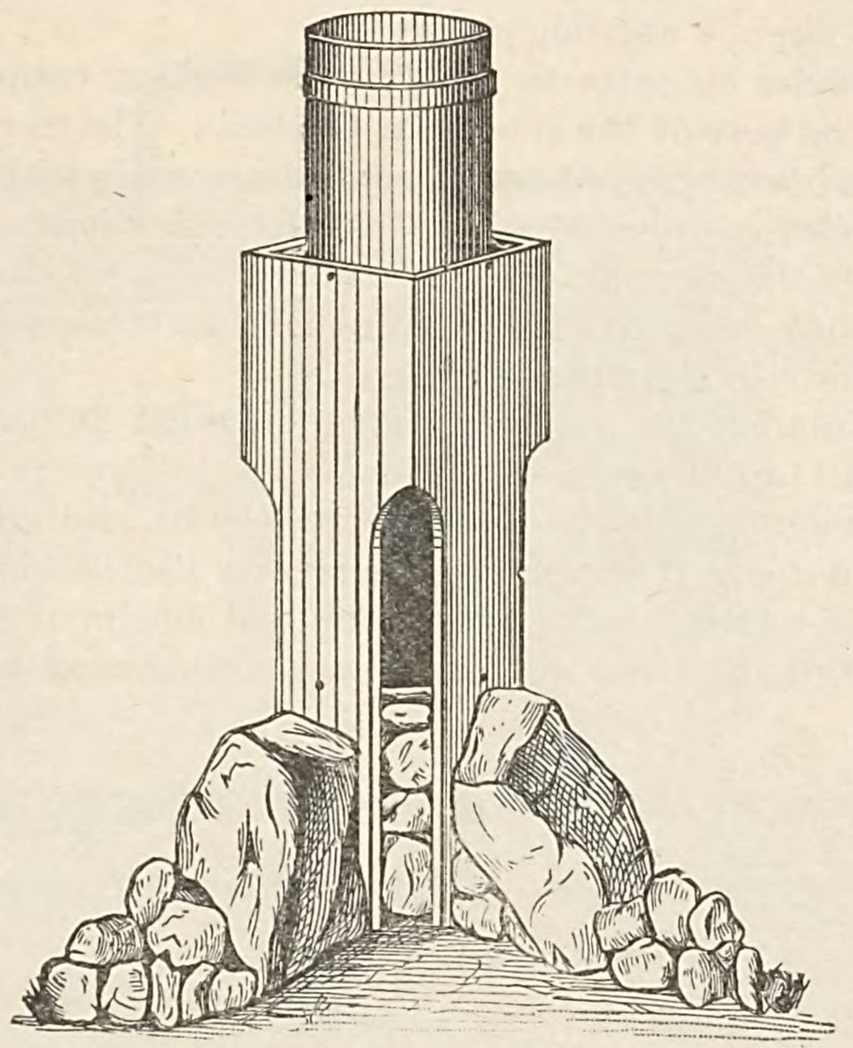

FIG. 13.—Rain and snow gauge, with ground support.

galvanized-iron vessel, or overflow, as it is generally called, is also 8 inches in diameter, and, in general, is used as a snow gauge during the winter season. Several forms of support are used for gauges. That shown in Fig. 13 is typical for a ground exposure.

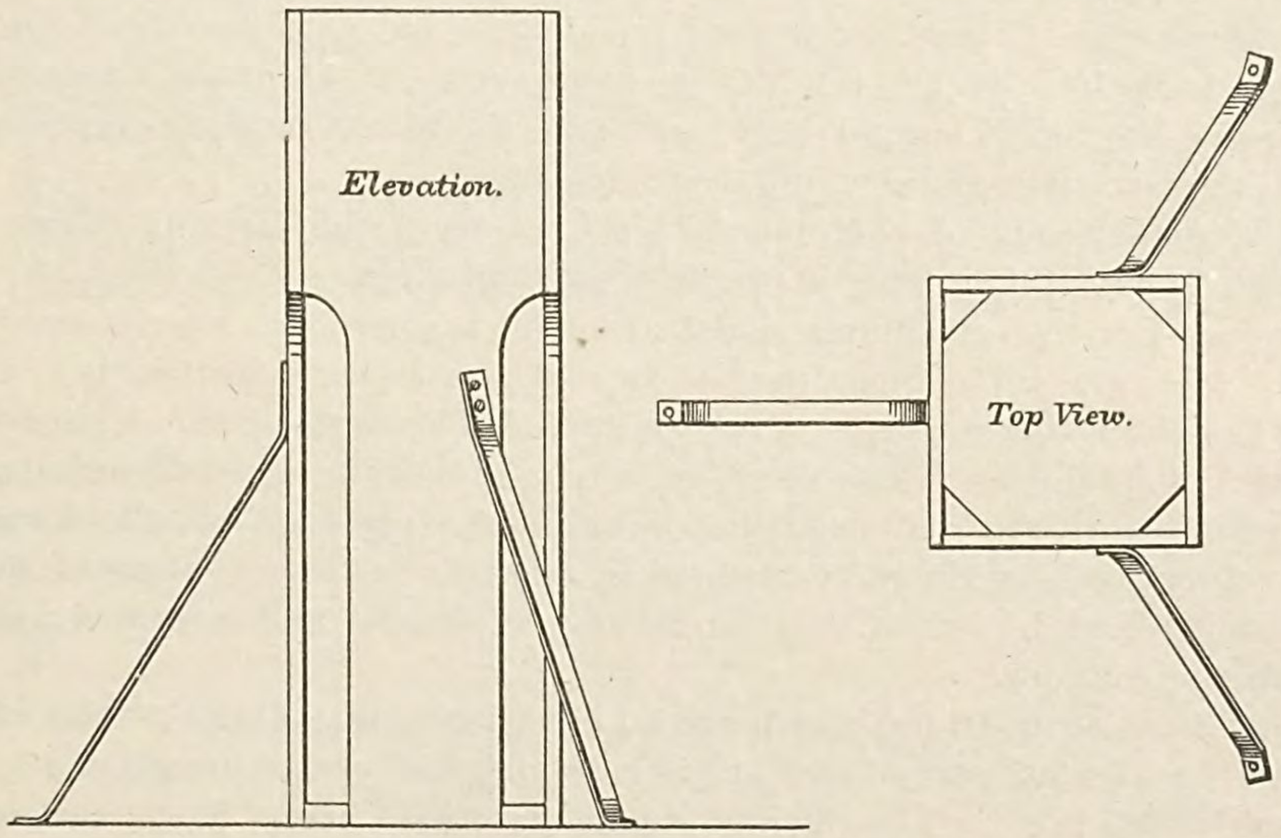

FIG. 14.—Rain and snow gauge supports.

Fig. 14 shows the method of supporting gauges on the roof.

Exposure of Gauges.—Rain and snow gauges at regular stations are generally exposed upon the roofs of buildings which are flat as far as possible, with the gauge near the center. In other

instances the gauge is properly protected from disturbing wind effects, but the exposures, in a few cases, are, at the best, more or less imperfect.

Thermometers.—Four thermometers are used in the regular daily observations, namely: One mercurial maximum thermometer and one alcohol minimum thermometer, mounted as shown in Fig. 15.

The two remaining are the ordinary mercurial wet and dry bulb thermometers. These latter are mounted upon a special form of whirling apparatus.

The maximum thermometer operates to register the highest temperature by virtue of the effects of a constriction in the bore of the tube near the bulb. The mercury is squeezed through under the action of rising temperature, but can not withdraw again with falling temperature.

The minimum thermometer is provided with a slender glass index sliding freely within the alcohol column in the stem of the thermometer. The index being set against the end of the alcohol column withdraws as the column contracts and remains at the lowest point reached, the alcohol flowing past the index for rising temperature.

The maximum and minimum thermometers have spherical bulbs. They are graduated to degrees Fahrenheit, about 12 to 16 degrees to the inch.

The wet and dry bulb thermometers have cylindrical bulbs, and are mounted upon a special whirling apparatus for the purpose of securing the necessary ventilation in making the humidity observations. Just previous to the hour of observation the muslin of the wet bulb is moistened and the thermometers whirled until the wet bulb reaches its lowest temperature, as shown by successive readings.

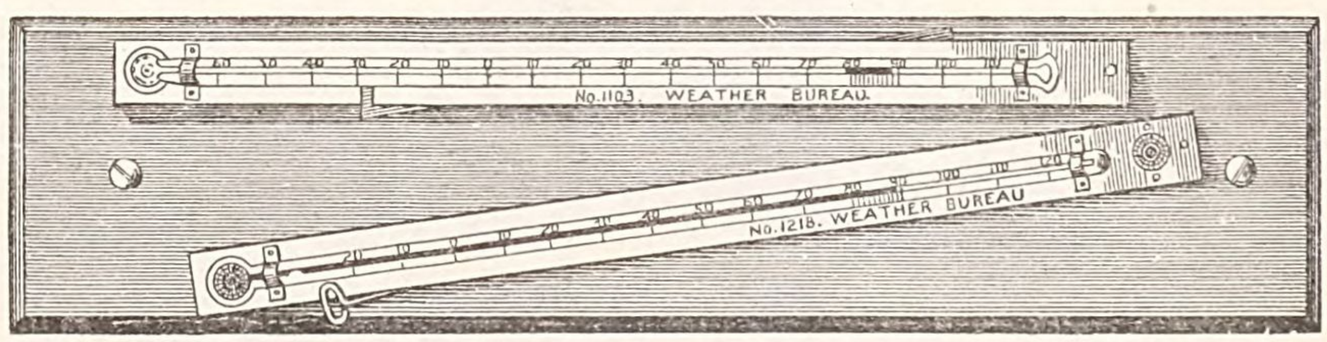

FIG. 15.—Maximum and minimum thermometers.

Each new thermometer, when received, is compared with the standard mercurials of the Bureau, and the correction for instrumental error determined so as to reduce all readings to the standard air thermometer. These corrections are determined at intervals of every ten degrees, 32°, 42°, 52°, etc., from the lowest to the highest temperature to which the thermometer is graduated, ranging from −48°, or, in special cases, −60°, for the lowest reading minimums to +112° for the highest reading maximum and dry-bulb thermometers.

Occasional recomparisons of thermometers are made at the freezing point, when sensible changes are found to have taken place after the first comparison.

Thermographs.—For the continuous registration of temperature the Richard thermographs have been used. (See Fig. 16). These, in a few special cases, record electrically at a distance. The construction of the plain thermograph is very simple. The metal bulb of the thermometer is curved and a very flat ellipse in cross section, after the fashion of the Bourdon pressure tubes. This is completely filled with alcohol or similar liquid, under pressure, which, changing as it does with varying temperatures, produces corresponding changes in the curvature of the bulb. These movements are magnified by suitable arrangements of levers, and inscribed upon a cylinder of paper in the ordinary manner.

In the case of the thermographs which record electrically at a distance the magnified movements of the thermometer are reproduced at the receiving end of the instrument by means of electrical mechanisms which are too complicated to be described here. These instruments, making their record always under inspection, leave little to be desired in point of convenience, but very few observers are thoroughly successful in keeping them in operation.

The record sheets are ruled to degrees, Fahr., one degree being about one-thirtieth of an inch, and the time scale is the same as for the barograph with lines for every two hours. The inaccura-

cies of the record due to small errors in time may be very great at times of sudden changes of temperature, and on this account the Weather Bureau has had made up special a number of thermographs in which the record cylinder makes two revolutions per week, and with the sheet ruled to hours, instead of every two hours. In nearly all cases these sheets are allowed to make two revolutions during the week. The thermal curves very rarely interfere, as the daily maxima for the last half occur with the minima of the first half of the week. The diagram, Fig. 17, is a copy of such a record.

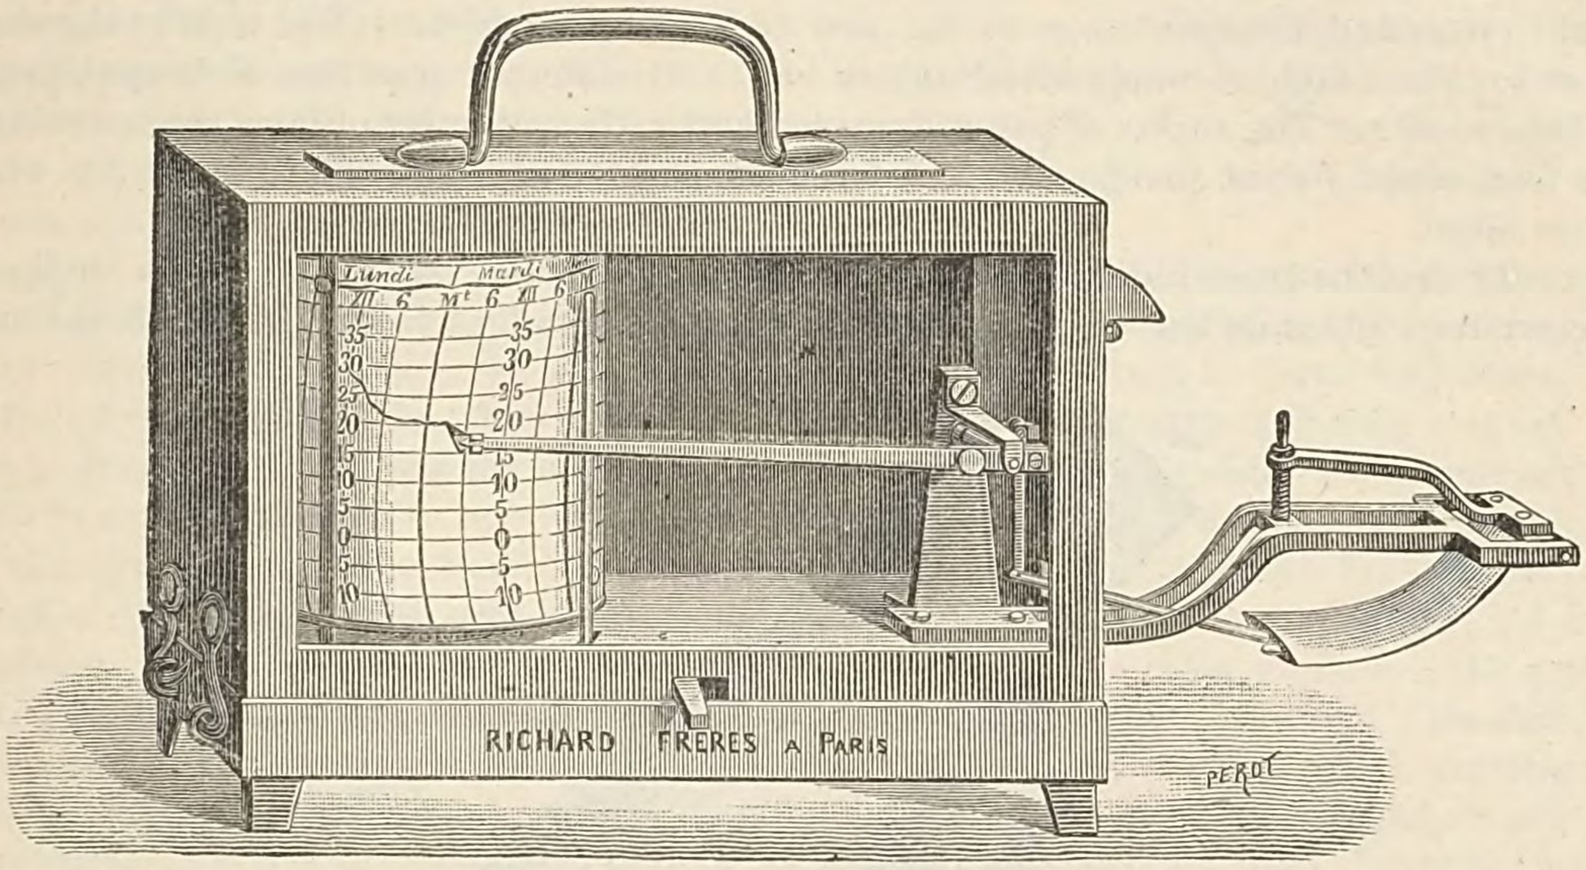

FIG. 16.—Richards thermograph.

Corrections for instrumental errors are worked out for the thermal traces in the same manner as described for the barograph, comparisons being made with eye readings of the whirled dry-bulb thermometers at 8 a. m. and 8 p. m., 75th meridian time.

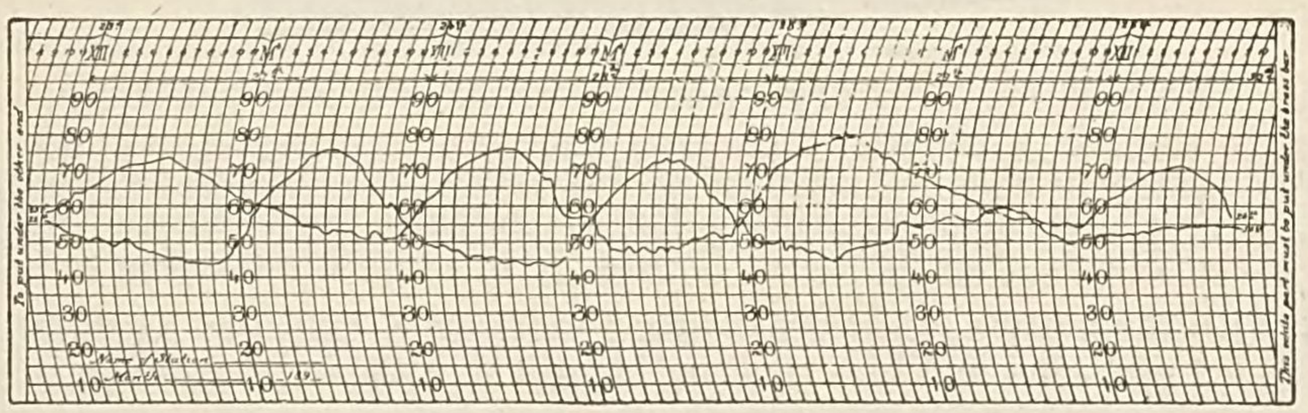

FIG. 17.—Semi-weekly thermograph curve.

Thermometer exposure.—The pattern of instrument shelter used almost exclusively for the past 7 years was first introduced by Prof. Hazen in 1885. The shelter measures very nearly 36 inches cube, inside; the roof is double and open on the north and south ends, sloping to the south at a small angle. The louvres are $3\frac{1}{2}$ inches wide, set 1 inch apart and at an angle of 45° to the vertical. The supports are generally about 10 feet high. With very few exceptions the shelter is placed upon the roofs of buildings freely exposed to the air currents, and removed from the effects of local influences. The sides of the shelter are placed north and south and east and west, respectively, and the bulbs of the maximum and minimum thermometers are near the eastern side of the shelter at about mid-height, while the whirling apparatus with the wet and dry bulb thermometers occupy the western half of the shelter.

Sunshine recorder.—The pattern of sunshine recorder used on stations is a modified design of the Jordan photographic recorder. Its construction will be understood from the illustration, Fig. 18. The large cylinder is adjustable in its supports, which are provided with a graduated arc by

which the axis of the cylinder, when adjusted properly north and south, can be made parallel with the earth's axis. This cylinder can also be entirely removed from the support without affecting the adjustment for latitude. The two sheets of ferro-prussiate paper adapted to receive the records of the forenoon and afternoon sunshine, respectively, are inserted at the bottom end of the instrument and made to conform to the concave surfaces of the segments of corresponding forenoon and afternoon cylinders within, as may be seen in the figure. The slides, *A*, *B*, are pierced each with a fine hole beveled out to a sharp edge and at a wide angle, thus permitting a small beam of sunlight to pass and form an image of the sun on the paper beyond. The hole in the slide *A* is shown at *h*. Each slide is notched and adjustable to 31 different positions corresponding to the days of the month. The sheets of paper are ruled vertically with a set of lines representing hours of time from about 4 a. m. to noon on the forenoon sheet and from noon to about 8 p. m. on the afternoon sheet.

In order that the trace indicating sunshine for any particular day of the month shall occur at a predetermined place on the sheet, notwithstanding the changes in declination of the sun from

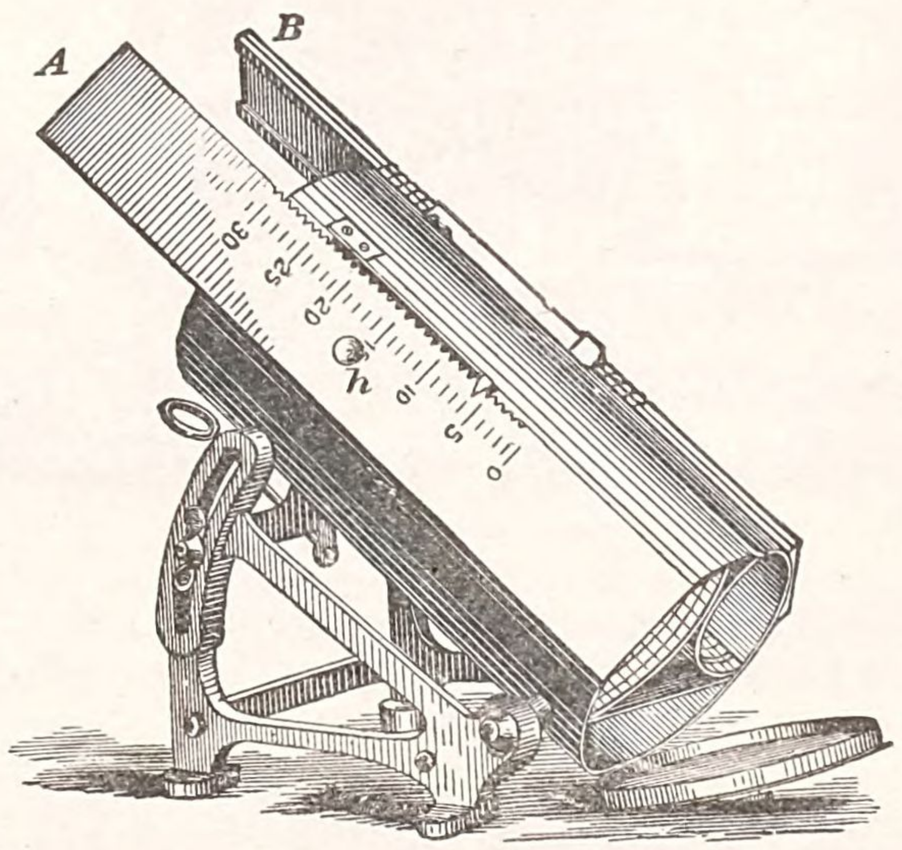

FIG. 18.—Sunshine recorder.

month to month, a series of lines are ruled across the bottom of the sheet, each line corresponding to a month of the year, and the position of the line so related to the declination of the sun for that month that if the sheet be cut off across the bottom at this line and inserted in the recorder with this edge flush with the bottom of the instrument the traces of sunshine from day to day will fall upon predetermined positions and can thus be identified with any particular day of the month, whereas, without this provision, if, for example, the first day or two of a month were cloudy and no record produced, uncertainty might arise as to the correct identification of the traces since these would occupy different positions on the sheet from month to month.

The use of this recorder has not been attended with much satisfaction, owing wholly to the imperfect and irregular action of the photographic paper. The best records are obtained from stations in the West, where there is a large proportion of bright sunshine and the air is comparatively dry.

Special instruments.—In addition to such instruments as have thus far been described, the records of hourly pressure and rainfall for the Washington office have been derived from instruments of special construction, designed and used only in that office.

The barograph (Foreman's).—This instrument was invented by Mr. A. L. Foreman in 1874, during his connection with the Signal Service. The barometer is of the siphon pattern, with a tube about three-fourths inch inside diameter. An iron float attached to the short end of a delicately poised lever rests upon the mercury in the short leg. The long end of the poised lever is tipped with platinum and plays between two platinum-tipped electrodes. The lever is connected

electrically with a battery. Either of the above-described electrodes connects electrically with a corresponding electro-magnet. These two electro-magnets actuate the same armature, but in such a manner that the one draws the armature in one direction while the other magnet draws the armature in the opposite direction. The terminal ends of the two electro-magnet coils—that is, the ends not connected with the platinum electrodes—are joined to each other and to the battery, thus completing the circuit. The delicately poised lever mentioned above, together with the two platinum-tipped electrodes, is mounted upon a nut moving upon a finely threaded screw A second screw, of much coarser pitch, is connected to the first screw by gears in such relation that the simultaneous movement of the nut on the coarse screw, which carries the pens that produce the record, is eight times as great as the movement of the nut on the fine screw The gearing by which these two screws are actuated is further connected, mechanically, with a train of gears driven by a suitable weight and locked by the armature of the electro-magnets.

The action of the mechanisms is as follows: Whenever the float in the short leg of the siphon is either buoyed up too much by a rise of the mercury or insufficiently supported in consequence of a fall of mercury, the poised lever will be deflected and thereby come in contact with one or the other of the platinum electrodes, thus sending a current through the corresponding magnet. The armature is drawn and releases the clockwork, so that a certain wheel makes one complete revolution and in such manner as to revolve the two screws above mentioned in a direction such as to readjust the equilibrium of the float and move the record pens. If equilibrium is not restored and the contact of the poised lever broken after one revolution, the action is repeated as long as contact continues. If the contact of the poised lever is made with the other electrode, the action of the clock is to move the float and record pens in the opposite direction The float, therefore, must always rise and fall with every variation in the level of the mercury surface, which variations are recorded on a magnified scale on the record sheets. In this instrument two cylinders are used, one revolving in 24 hours, giving a time scale of about 0.65 of an inch per hour, the other cylinder revolving only once in 16 days. The pressure scale on the sheets is subdivided to represent 0.02 inch, being a fourfold magnification.

The performance of this instrument is, on the whole, very satisfactory; still, when the most minute accuracy is required it becomes unreliable. There is entirely too much lack of rigidity in the mounting of the float mechanisms in relation to the mercurial surface, in consequence of which false movements of the pens are possible. Moreover, the system of mechanisms and barometric heights of the mercurial column is not independent of temperature changes.

The pens are adjusted as nearly as may be to the correct pressure when new sheets are placed in position, and the true pressure, as given by a standard barometer, is noted on the sheet each 24 hours. The final hourly readings taken from the sheet are adjusted to conform to the eye readings in the manner already described. These readings are entered in the nearest hundredth inch only.

Recording rain-gauges.—Two special pluviographs have been in use at the Washington office for many years, though the rainfall trace, or record from one of these, known as the Gibbons gauge, being made by the abrasion of a strip of silver upon so-called metallic paper, after the method introduced by Beckley in his anemograph, was so faint and imperfect as to be quite unreliable. The rain-gauge was reconstructed during the past year and a much more perfect ink record secured.

A third gauge of improved pattern was also used during a portion of the year, and with much success. The greater part of the past records have, therefore, been derived from but one gauge, known as the Eccard gauge. The construction and exposure of this will be understood from Fig. 19. The receiver of the gauge is 12 inches in diameter and constructed with an enlarged bowl beneath for the purpose of better retaining the snow that should enter the mouth of the gauge and that might otherwise be blown out. The bowl of the gauge is encased in a wooden boxing passing entirely through the roof and communicating with the rooms below, thus providing a flue for the passage of the warm air from the room to the bowl of the gauge, which is thus warmed to such an extent that, except in rare cases of very cold weather or very heavy snowfall, all such precipitation is melted as it falls. The bowl of the gauge is connected by a block-tin tube with

the measuring cylinder attached to the registering part of the gauge, in the office below. The registration is effected as follows:

A counterpoise *c*, Fig. 19, carries the tracing pen, or pencil, which marks against the record cylinder in the usual manner. The counterpoise slides freely between appropriate guides and parallel to the axis of the cylinder, being sustained by a thread passing over pulleys and fastened to

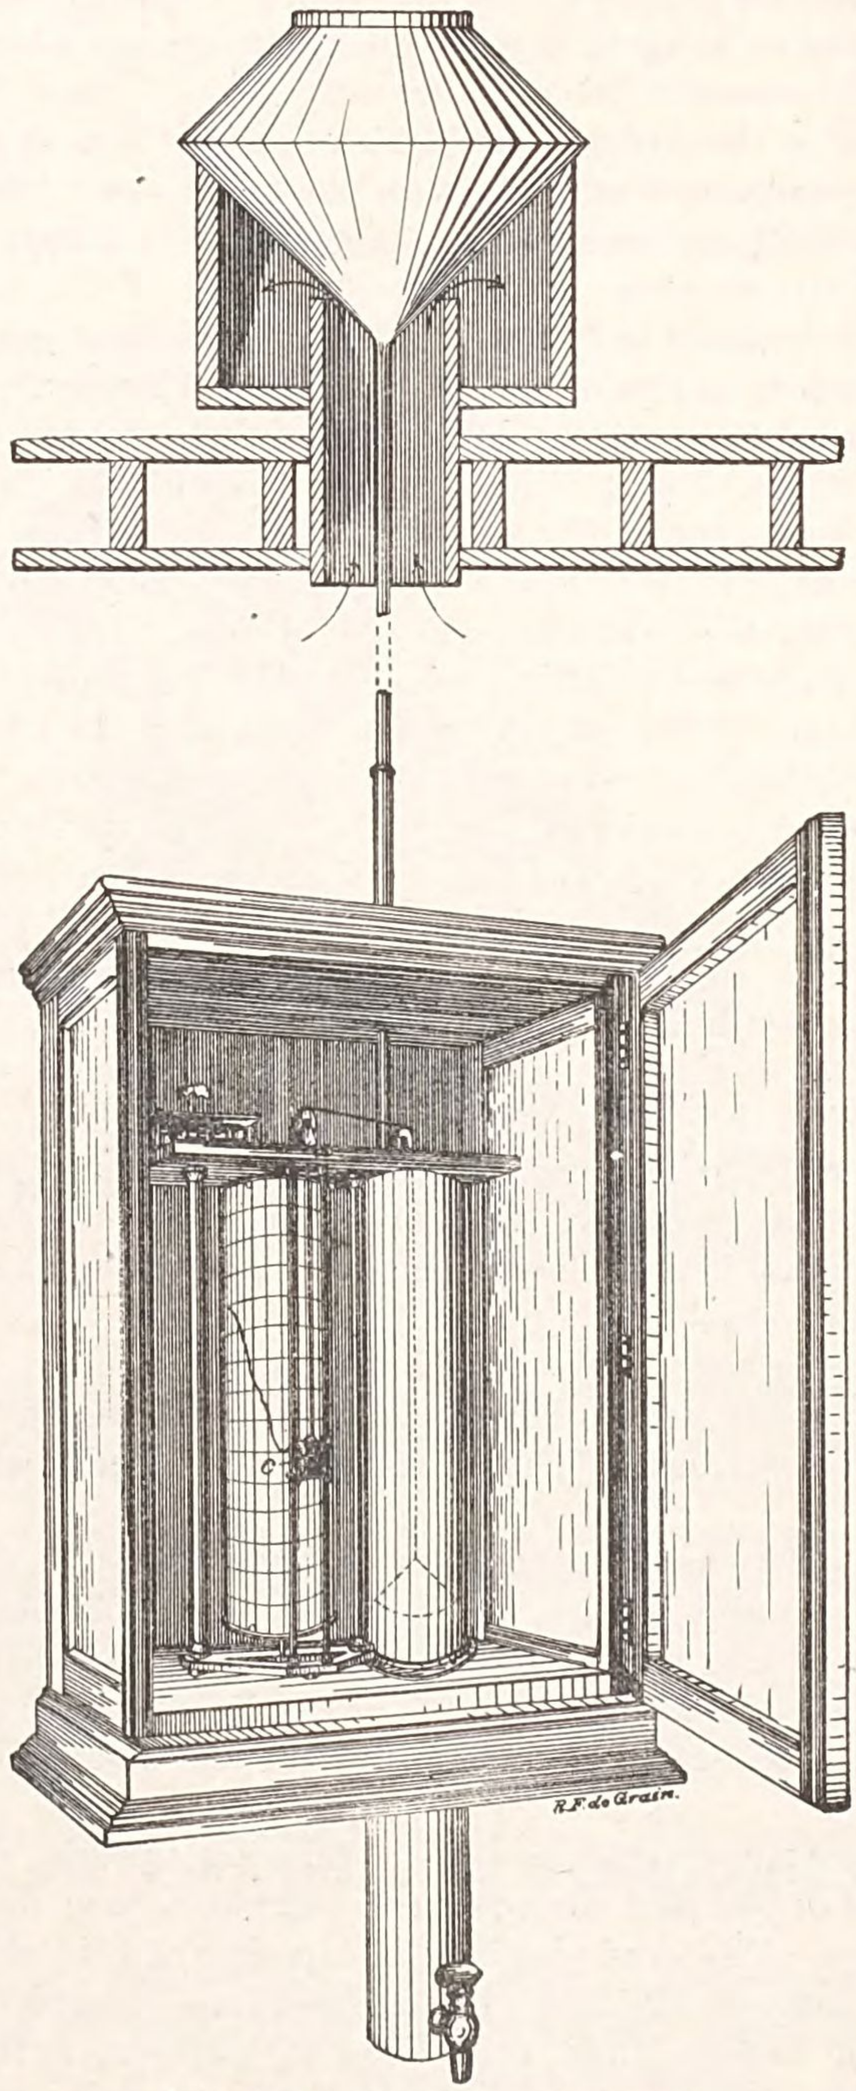

FIG. 19.—Eccard recording rain-gauge.

a float resting upon the water surface in the measuring cylinder. As the water surface rises the counterpoise descends half as far, but still with a five-fold magnification of the actual precipitation. The time scale on the record sheet is subdivided into hours only, at the rate of one-half inch per hour, the vertical scale being subdivided only to half-inch spaces, representing one-tenth inch of precipitation.

All gauges of this type—that is, in which the bowl is artificially warmed to any extent whatever and in which the water is conducted a distance through a long tube for measuring—are open to serious objection and show a deficiency of precipitation. Prolonged drizzling rains and light snows may be entirely evaporated and not recorded. An uncertain loss and delay of record also arise in the action of the water wetting the conducting tube before making its way finally into the measuring tube.

The Gibbon gauge, as it is now constructed, is much superior to the Eccard gauge, and is described below. The alterations related entirely to the registering mechanisms, with the exception that the warming flues for heating the bowl of the receiver so as to melt snowfall were discarded. The gauge, therefore, now records only rainfall, and, as it is, some few hundredths of inches are always lost in wetting the long tube.

The registering mechanisms are actuated electrically. A float rests upon the surface of water in the measuring tube; its supporting thread passes first over a guide wheel which is at one end of a lever poised freely upon knife-edges. The opposite end of the lever is weighted and when the tension on the float thread is relaxed the weighted end of the lever falls upon a platinum-tipped screw, thereby closing an electric circuit through an electro-magnet forming part of the mechanisms. The float thread, after passing over the lever wheel, has its end fixed to a small drum upon a suitable axis. Upon this same axis is also secured, first, a pair of ratchet wheels and, second, a large gear wheel. A pawl attached to the armature of the electro-magnet engages the teeth of one of the ratchet wheels in such manner that the wheel is revolved tooth by tooth by the vibratory action of the electro-magnet. The second ratchet wheel serves merely as a locking mechanism to prevent the wheels being ever revolved more than just one tooth at a time. The above-mentioned large gear wheel communicates motion to a small gear fixed upon the extremity of a large right and left hand threaded screw, having only two threads to the inch. The nut upon this screw carries a long adjustable pen arm and pen, which may be placed in gentle contact with the record cylinder.

When the nut is set at one end of the right and left hand screw, the action of the double thread is such that when the screw is revolved continuously in one direction the nut passes regularly back and forth across the screw from end to end, the motion of translation at all times being strictly proportional to the motion of revolution. The slight departure from absolute proportionality that occurs at the ends of the thread is reduced to a minimum and is quite insignificant.

As long as the tension on the float thread is sufficient to depress the wheel end of the poised lever, the electrical circuit is broken at the opposite end of the lever. When, however, a perceptible rise of water occurs in the measuring tube the float is buoyed up, the tension relaxed slightly, and the weighted end of the poised lever makes contact and closes the electric circuit, whereupon the ratchet wheels are advanced one tooth by the action of the electro-magnet, the float thread wound up a little, and the pen advanced a proportionate amount.

Other very simple yet ingenious mechanisms, not here described, are attached to the armature of the electro-magnet and operate in such manner that a very slight and momentary closure of the circuit at the lever contact is sufficient to produce a complete movement of the armature, which, after being once started, operates by virtue of a circuit independent of the one through the lever contact. This circuit can not be opened until the armature reaches its lowermost position, and the circuit can not then be closed again until the armature has returned to its highest position. If, however, the winding up of the float thread due to one stroke of the armature is not sufficient to lift the depressed contact lever, the armature upon its return will immediately take a second, and, in rapid succession, a third and many other strokes until the circuit *is* broken.

The action of these mechanisms has proved extremely reliable.

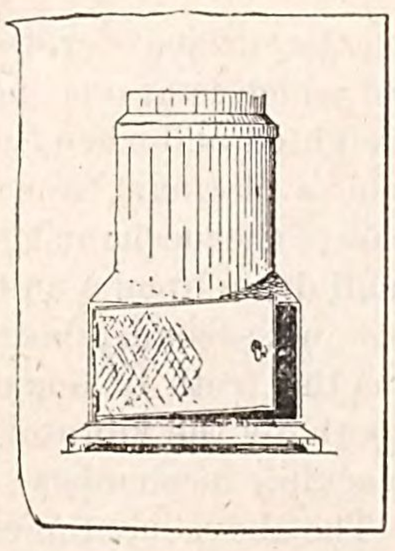

The magnification of the precipitation record is tenfold, that is, 0.1 inch on the sheet represents 0.01 inch of rainfall and the scale is subdivided to represent hundredths of inches. The pen will pass entirely across the sheet from side to side for one-half inch of rainfall. The sheet makes two revolutions in twenty-four hours, and, if no precipitation occurs, the pen during the last twelve hours retraces the line followed during the first twelve hours. The sheets, in general, are not changed except after precipitation, but the pen is set each day to trace a new line so that every day has its record whether rain occurs or not.

The time scale is subdivided into ten-minute spaces, from which minutes are easily estimated. When in normal action, during rainfall, one movement of the electro-magnet is always sufficient to break the contact, notwithstanding that this movement represents only one-quarter of one one-hundredth inch of precipitation.

Marvin's Weighing Gauge.—It is quite evident that at once the simplest and most accurate method of measuring snow is by weighing the quantity collected within or upon any given receptacle. No loss need occur in this method either from evaporation or by melting processes or in the wetting of conducting tubes, etc. Even the bowl of the gauge may be dispensed with, allowing the precipitation to pass at once into the receiving vessel. The method is equally applicable to registration of rainfall.

It is very undesirable to subject the clock movements and other parts of registering mechanisms to all the extremes of heat and cold, rain and moisture, of outdoor exposures, although this is done in some cases.

In the form of gauge described here, however, the precipitation is automatically and almost continuously counterpoised upon a sensitive balance and the amount simultaneously registered, electrically, within the office. The weighing mechanism consists of the usual balance on knife-edges with a beam and sliding counterpoise. The movement of this counterpoise is effected by means of a long screw set parallel to the beam upon which the weight slides. This screw is caused to revolve and move the weight by the vibratory action of the armature of an electro-magnet. The balance, with the receiving vessel in position, is adjusted by hand to a condition of equilibrium. No action ensues until the end with the receptacle becomes heavier, whereupon the deflection of the beam of the balance closes an electric circuit through the electro-magnet. When the armature of this magnet moves a little its own circuit is closed independently of the contact at the beam, and, with the object of securing registration, a second and separate circuit is closed through an electro-magnet on the register. These two circuits are closed during the first slight movement of the armature on the balance. During the further movement of this armature the screw actuating the sliding weight is revolved slightly and the weight moves so as to restore the equilibrium. The armature, however, after moving the weight, can not return until a corresponding movement has taken place in the pen of the register. To secure this the electric circuit which includes the electro-magnet on the balance is passed through the armature of the magnet on the register in such manner that the circuit is broken whenever the armature of this magnet is attracted, but only at a moment just before the movement of the armature is completed. The breaking of this circuit, however, does not interrupt the current flowing through the register magnet. This circuit is

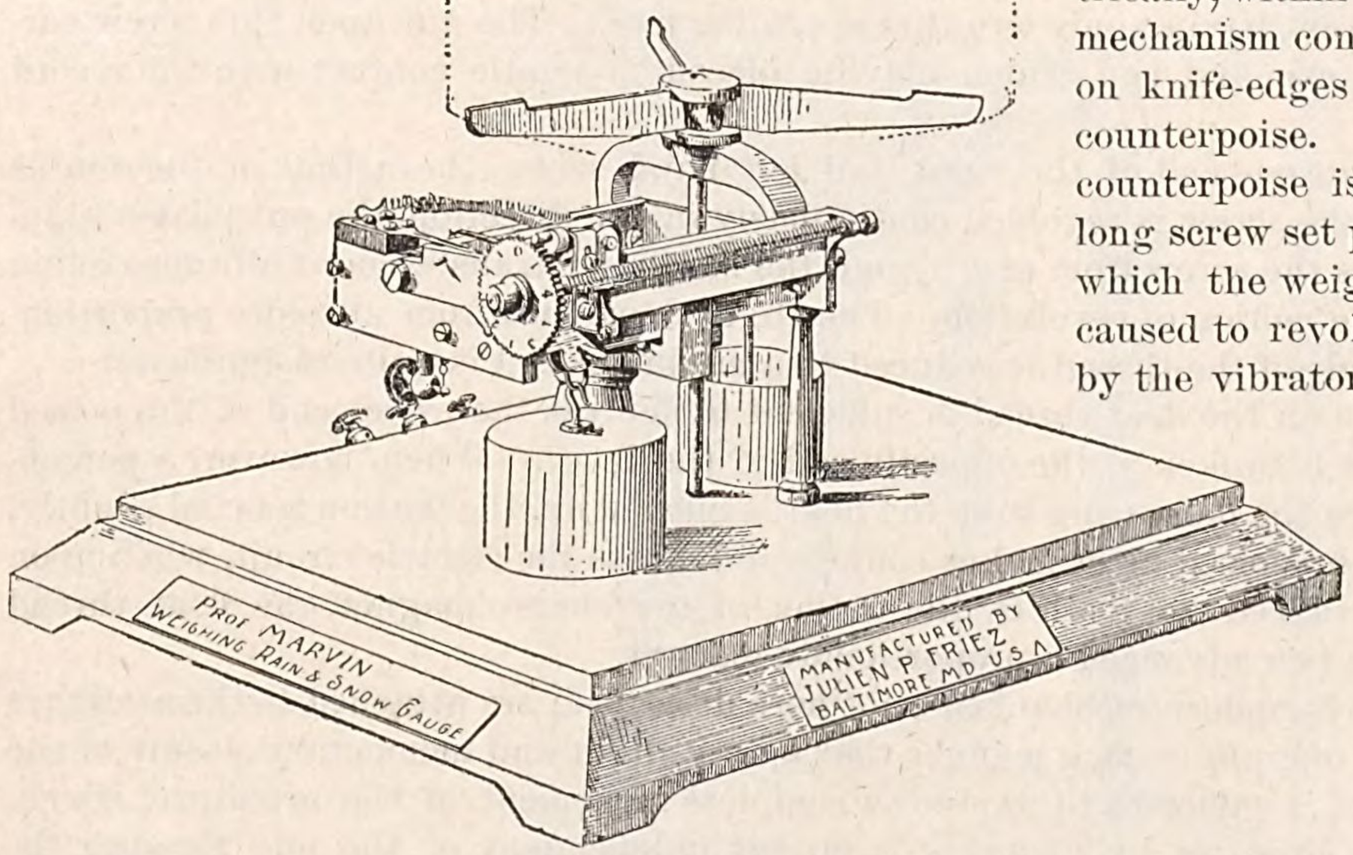

FIG. 20.—Weighing rain and snow gauge—receiving mechanism.

broken only when the armature of the balance magnet, having been drawn is released, and returns to its normal position, whereupon the register magnet releases its armature, which also returns to its normal position, and, in doing so, closes again the break it had made in the circuit through the balance magnet.

By the arrangement of circuits and mechanisms thus described, complete synchronisms in the action of the two magnets is secured, each movement of the weight being accompanied by a corresponding movement of the recording pen.

This gauge is shown in Figs. 20 and 21. The cover of the receiving mechanism, attached to the base and with door ajar, is shown in small cut at left, Fig. 20.

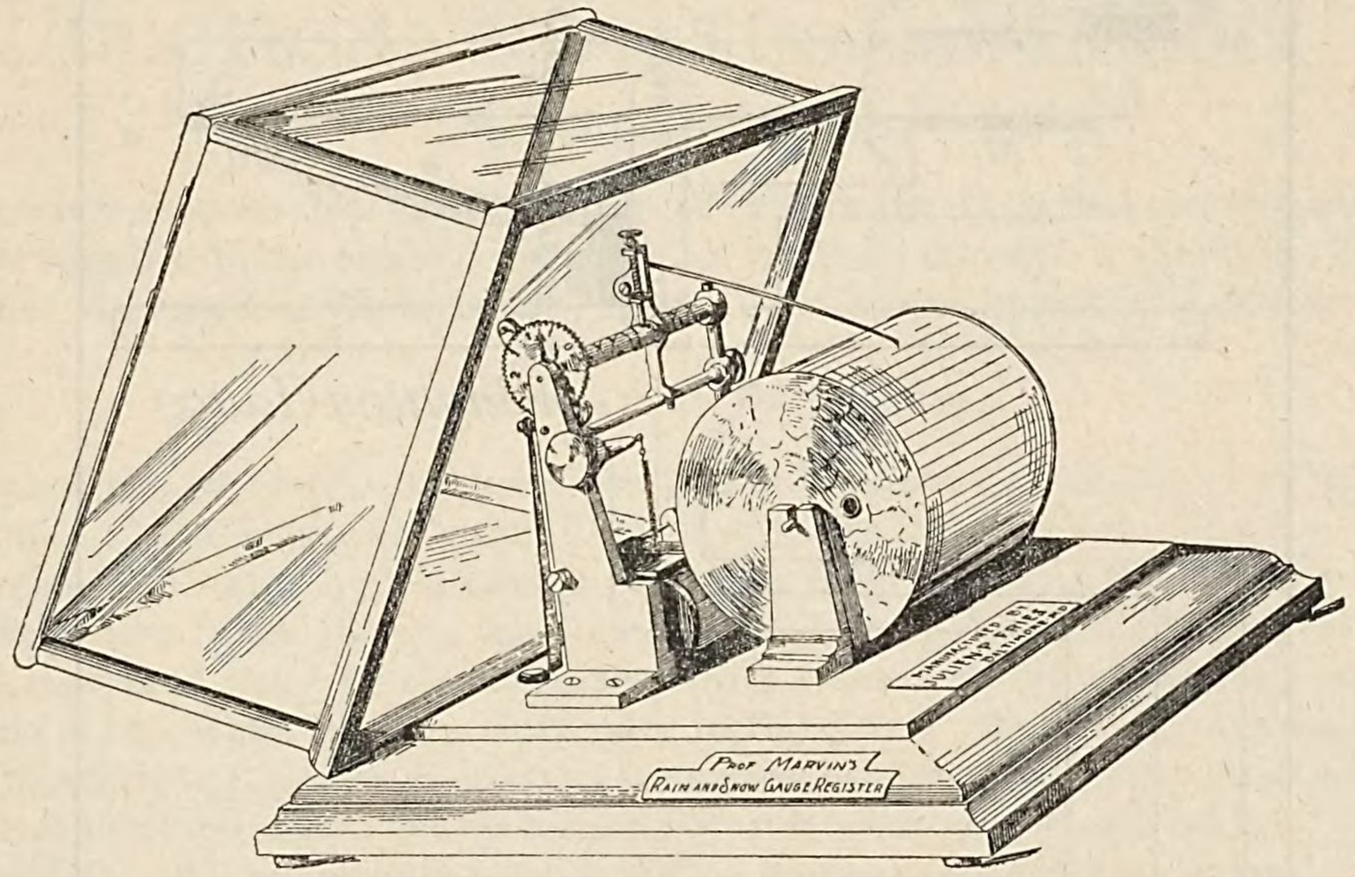

FIG. 21.—Weighing rain and snow gauge—recording mechanism.

The following explanation of circuits, in connection with Fig. 20, will enable the reader to better understand the action of the gauge:

Three wires and one battery are required. One pole of the battery is connected to the gauge at *B;* the other pole is joined to the register at *A*. The remaining posts are joined, No. 1 to No. 1, and No. 2 to No. 2.

The action is as follows: When the equilibrium is disturbed the circuit is closed at *d*. This contact is often light and momentary in character. The armature of the magnet, however, is free to move a short distance with only slight resistance, and during this initial movement closes a circuit firmly and permanently, insuring thereby the complete attraction of the armature and a corresponding movement of the counterpoise. The armature also closes a second circuit at the register contact spring *b*. The current at this instant divides, part flowing through the magnet *M* on the gauge and an equal part passing through the magnet coil *N* on the register. When the armature of the register magnet has made its movement, the current through circuit No. 1 is interrupted at the contact pin *m*. This releases the armature of the magnet *M* on the gauge, and when said armature has returned to its normal position the circuits through the contact springs *c* and *b* are each broken. When the No. 2 circuit through *b* is broken the register armature is released, closing again the No. 1 circuit at *m*.

If by these actions the equilibrium of the balance has been restored the contact at *d* will have been broken. If this is not the case, however, the cycle of actions will be repeated over and over again until the circuit is broken at *d*.

The construction of the register is, in a slight degree, similar, but much simpler than the corresponding parts of the modified Gibbon register. The armature of the electro-magnet engages directly a notched wheel upon the right and left hand screw, and in such manner as to cause it to revolve tooth by tooth, always in one direction. The sleeve nut upon the screw carries an adjustable pen arm and pen in the usual manner.

The receiver of these gauges is 8 inches in diameter. A single stroke of the magnet moves the sliding weight only one eight-hundredth part of an inch and represents one one-thousandth inch rainfall; that is, about 0.82 gram. The record pen for one stroke of the magnet moves one one-hundred-and-fiftieth part of an inch; that is, the scale of precipitation is magnified $6\frac{2}{3}$ times. The pen will pass once across the sheet for each one-half inch of precipitation, and the sheet is sub-

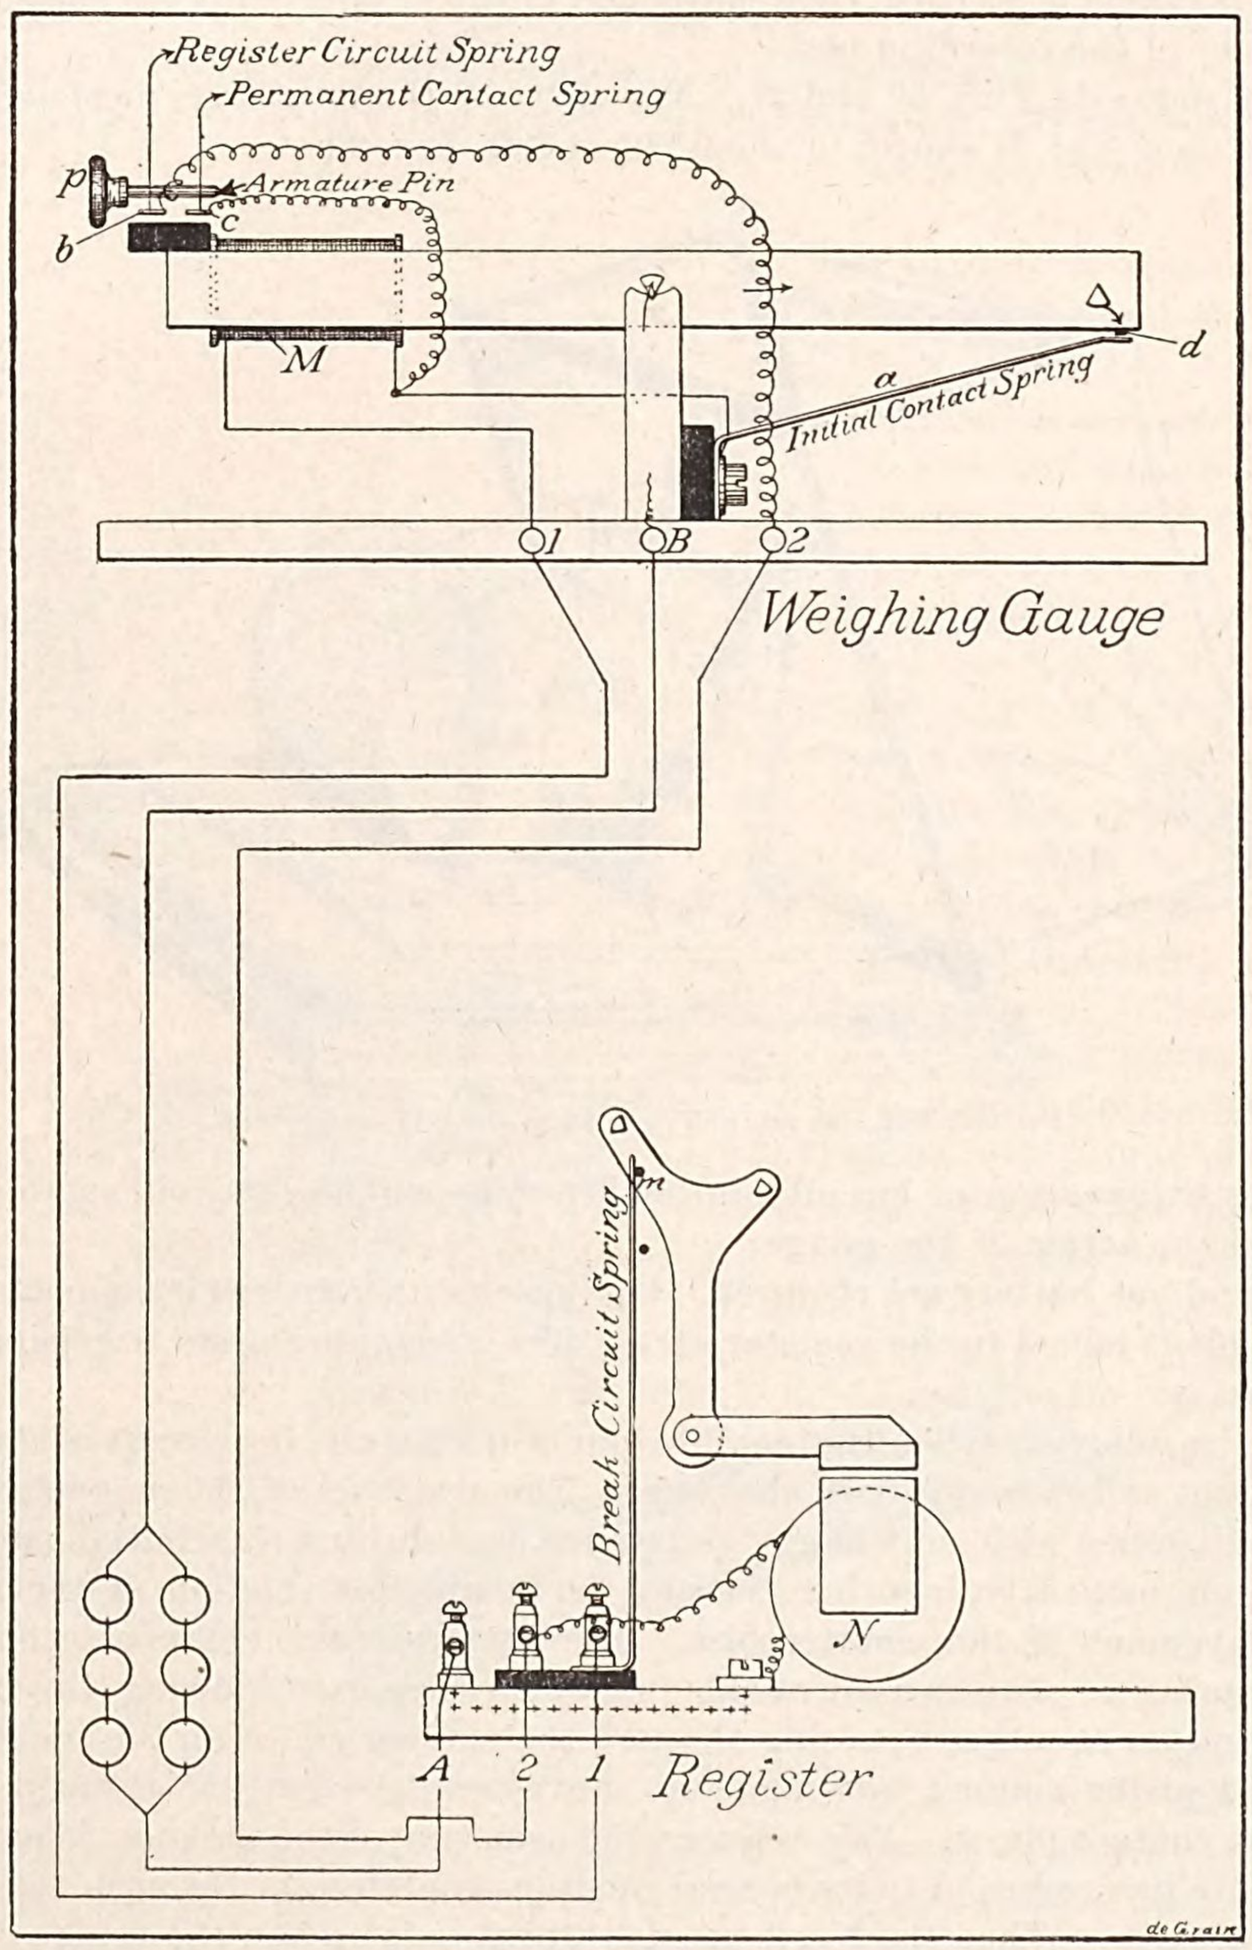

FIG. 22.—Conventional diagram of circuits.

divided to represent hundredths of inches of precipitation. The cylinder is 12 inches in circumference and revolves twice in 24 hours. The sheet is subdivided into ten-minute spaces, and minutes are discernable.

In the normal action of the gauge the electro-magnets rarely or never make but one stroke to restore a condition of equilibrium, notwithstanding that this represents only one one-thousandth of an inch of rainfall.

INSTRUMENTAL CORRECTIONS; METHODS OF REDUCTION; RESULTING ACCURACY.

By Prof. CLEVELAND ABBE.

The respective sections of the present chapter explain the numerical corrections or reductions that have been applied to the original instrumental readings in order to obtain the data published in this volume. A general estimate is also given of the accuracy that attaches to the numbers here given.

TEMPERATURE OF THE AIR.

(1) *Thermometric standard.*—The standard of the Weather Bureau is the air thermometer of constant volume and is identical, within 0.02° C. or 0.05° Fah., with the standard of the International Bureau of Weights and Measures at Paris. This standard was decided upon in 1881 and definitive action taken during the months of July to November, 1882, when Prof. Thomas Russell first compared three substandard mercurial thermometers with the air thermometer of Prof. Rowland of the Johns Hopkins University in Baltimore. Since that year the thermometers issued from this bureau have been carefully compared at each ten-degree point with those and other mercurial substandards. The corrections thus determined within a tenth of a degree Fahr. reduced all Weather Bureau observations to the air thermometer and were actually applied by the observers to all their observations and the official observations were made and the records were kept to the nearest tenth degree, until January 1, 1888, when, in order to diminish the work of our observers and in view of the fact that no thermometer was issued whose corrections exceeded one-half of a degree Fahr., it was ordered that in using such thermometers the known scale corrections be neglected when they are only 0.3 or less. Consequently the records in the present volume for the years 1891–'92 have an outstanding uncertainty, due to the scale errors, that may be assumed as equal to the average amount of these neglected corrections, plus the secular rise of the zero point, plus an additional uncertainty whenever the temperatures have exceeded or fallen below the range for which the thermometers had been accurately investigated, *i. e.* below —28° and above 112°. During the winter season it occasionally happens that unusually low temperatures occur at stations whose thermometers have not been tested for such extremes. In these cases an extrapolated correction has been used as being the nearest approximation available. So far as the accuracy of the thermometer is concerned it will be possible, in future years, to apply the known corrections throughout the length of the scale. Under the present system the uncertainty due to scale corrections is for the dry and wet bulbs plus or minus 0.2; for the maximum thermometers plus or minus 0.2; for minimum temperatures plus 0.4; the plus correction for the minimum thermometer increases as the temperature falls and as the alcohol has less time to drain downwards.

(2) *Ordinary station mercurial thermometers.*—The observations whose monthly means are given in Parts II and III, for 8 a. m. and 8 p. m., standard time, have been made personally by each observer on eastern, or seventy-fifth meridian, time and are the fundamental simultaneous observations made primarily for use on daily charts for weather predictions and atmospheric studies. The temperature of the air is deduced from the readings of the whirled, dry-bulb thermometer, which is a part of the whirled psychrometer established in the light wooden thermometer-shelters originally known as the "Hazen" shelter; this shelter was introduced into the service as the result of the investigations made by Prof. H. A. Hazen in 1885 and replaced the large double louvre shelter that was adopted in 1870. These thermometers are all made of uniform pattern,

having cylindrical bulbs about 0.8 inch long and 0.2 inch in diameter they are graduated on the glass stem, and the endeavor has been to secure for the use of Weather Bureau stations thermometers whose errors shall not be greater than one-half degree Fahr., within the range of temperatures at which they are ordinarily used; all the thermometers are appropriately tested at the time of their purchase in order to insure their accuracy in this respect. The thermometers purchased for Weather Bureau stations also fulfill the condition that they shall have been filled eighteen months before graduation, so as to insure approximate stability of the 32° point.

(3) *The thermometer shelter.*—The Weather Bureau shelter is a cube of about 1 yard on a side, having a sloping, double roof, closed bottom, and single louvre sides. As this shelter is exposed freely to sunshine, wind, and rain there is an occasional possibility that the thermometers are wetted by the rain. Whenever such is the case a note is made on the record and the readings are entered as made.

The heat of the sunshine on the side and the top of the shelter, as well as the impediment offered by the slats to the free circulation of the wind, as also the gentleness of the natural current of air that flows past the thermometers, all tend to make the latter give a higher reading than belongs to the free air at the same level outside. Numerous experiments by Prof. Hazen appear to have shown that the errors thus introduced into the monthly means of the maximum and minimum temperatures by the peculiarities of the shelter, as such, will not exceed a degree at midday in the climate of Washington; similar investigations in Europe confirm this conclusion.

Both temperature and moisture of the air are determined more accurately by mounting the dry and wet bulb thermometers upon a pair of arms that can be rapidly revolved. The whirled psychrometer thus mounted, within the thermometer shelter and in close proximity to the maximum and minimum thermometers, undoubtedly gives the average temperature and moisture that prevail within the shelter at the time. To what extent these conditions within the shelter differ from those outside may be inferred from corresponding observations made by Prof. Hazen with the naked sling thermometer just outside of the shelter, or from the observations made by Wild with his ventilated shelter, in which the artificial ventilation rapidly renews the air within the shelter, or from those made by Assmann, in which the aspiration psychrometer is adopted as the standard. If any wind is blowing while the observer is whirling the psychrometer within his shelter, the result will be very much the same as in the use of Wild's "shelter with ventilator" and the observed temperature and moisture must be considered as that of the free air to within half a degree Fahrenheit. If, however, a calm prevails during full sunshine the Weather Bureau temperature may be too high and the relative humidity correspondingly too low. As Assmann's newest form of ventilated psychrometer with rapid ventilation gives results free from error due to the shelter and is more convenient than the whirled or sling thermometers it is now recognized as the ultimate standard in meteorology, and any equivalent apparatus that can be economically constructed may be adopted for use at ordinary meteorological stations. It is not likely that the monthly means or the daily temperatures recorded in Parts II and III of the present volume differ in any individual case by more than one-half of a degree Fahrenheit from what would be given by such a standard ventilated shelter or ventilated pyschrometer at the same altitude above ground.

(4) *Altitude of shelter.*—That feature of thermometer exposure which most affects the extremes of temperature, as recorded by the Weather Bureau, is the altitude of the thermometer-shelter, and that, too, not only above the roof of the building and above the ground at its base, but especially in its relation to the topography of the ground for several miles around the station. As the Weather Bureau thermometers are established at an elevation of 10 to 15 feet above the roofs of high buildings, or, failing these, 15 feet above some elevated ground, and are therefore exposed to any breeze that may blow, therefore the maxima, or midday, temperatures are not often so largely affected by the height above ground as are the minima or nocturnal readings. During calms, and especially during calm nights, the cold air settles in the lowlands and flows down river valleys and ravines as fast as fresh, cool air can be supplied from above. Thermometers stationed on high buildings are often entirely above the layer of cold air near the ground beneath them, and similarly with the thermometers in low valleys as compared with those on bluffs and hills near by. Consequently minimum temperatures, as reported from regular Weather Bureau stations, which are

always elevated as much as possible above the surrounding region, are appreciably higher than those reported from voluntary stations in the neighborhood, since the latter are almost invariably near the ground. No correction has been made for this source of discrepancy; the very object of exposure at such altitudes above the ground as are adopted by the Weather Bureau is to obtain an approximation to the average temperature of a large mass of air flowing by the station and forming an integral part of the circulation around the areas of high and low pressure; the temperatures thus observed are especially adapted to the needs of dynamic meteorology, whereas those observed by thermometers nearer the earth's surface are appropriate to the study of climate in its relations to animal and vegetable life within very restricted areas.

(5) *Influence of large cities.*—The fact that the Weather Bureau stations are located in the midst of cities tends to elevate both the maximum and minimum temperatures above the values that would obtain in the surrounding open country and thus elevates the annual and monthly mean temperatures. For thermometers that have perfectly similar exposures and are at the same heights above ground, this influence is appreciable in such large cities as London and Paris; but it diminishes with the height of the thermometers above ground, and especially with an increase in the average force of the wind. This effect is probably inappreciable in such a case as Chicago, where the Weather Bureau thermometers are 241 feet above ground and where the annual movement of wind is quite large. No correction has been applied to the published observations for this feature in the location of our thermometers.

(6) *Maximum temperature.*—The maximum thermometer is of the mercurial Negretti and Zambra pattern, having the bore of the tube constricted below the bottom of the scale. This style of thermometer is subject to the following corrections: (1) The mercury does not rise above the constriction except by virtue of a pressure from below, and if, at the time of maximum temperature, the rise of temperature is quite slow, as is usually the case, it is quite possible that the capillary resistance at the constriction will prevent the registration of the rise during the last tenth of a degree; therefore, strictly speaking, the maximum registered temperature may on the average be about 0.1° F. below the truth. On the other hand, when the temperatures are quite low and the column of mercury above the constriction is quite short, then the capillary action at the lower end of the column tends to elevate the mercury and to give too high a reading. Finally, the fact that the maximum temperature is registered in the warmest part of the day while the reading is made at a subsequent cooler portion causes the reading to be too low, owing to the contraction of the mercurial thread. The maximum thermometers, whose records are here given, have not been corrected for any of these sources of error, but special samples of these maximum thermometers have been studied sufficiently to insure against the probability that any error, amounting to half a degree Fahrenheit, has been introduced. The actual readings are always made to the nearest tenth of a degree; they are made and recorded twice daily, at 8 a. m. and 8 p. m., standard time, and the index is set daily at 8 a. m. If the maximum has occurred between 8 p. m. and 8 a. m., collateral evidence is at once obtained by the observer, who credits the maximum to the proper date, so that the maxima here published represent the highest temperatures during the twenty-four hours of the civil date, on eastern standard time reckoning, to which they are accredited.

(7) *Minimum temperature.*—The minimum temperatures are recorded by the "Rutherford" alcohol minimum thermometer. The instrument is read twice daily, but is only set at 8 p. m., standard time. Owing to the fact that at Washington the morning minimum occurs before 8 a. m., but at San Francisco after 8 a. m., standard time, which is 5 a. m. of local time, it can easily happen that no proper minimum is recorded at the Pacific and Rocky Mountain stations at 8 a. m., eastern time, and that the minimum thermometer, in fact, at that moment agrees with the ordinary thermometer. This trouble is remedied by the requirement that the observer shall read and record his minimum thermometer at both the observations at 8 a. m. and 8 p. m., and the true daily minimum is frequently given by the 8 p. m. observations; in all cases the published minimum belongs to the civil date, standard eastern time reckoning, for which it is given. This class of thermometer is subject to errors, due to an evaporation or diffusion from the alcohol column, and especially to the adhesion of the alcohol to the upper end of the tube; the temperature record may therefore be too low, but numerous experiments on the so-called drainage error have failed to

show any satisfactory method of correcting this error, except by long waiting, which is not practicable.

(8) *Hourly records by thermographs.*—Continuous records of temperature are made by means of the thermographs manufactured by Richard Bros. of Paris. The space upon the record sheet corresponding to 1° Fahrenheit is about 0.03 inch. This instrument is only a differential apparatus, and its indications are frequently checked by comparisons with the readings of the mercurial thermometer in the same shelter. In transcribing the hourly values of the temperature, the plan followed, which is almost identical with that adopted in reading off the barograph sheets, is as follows: The 8 a. m. and 8 p. m. personal readings of the standard whirled psychrometer, located in the same thermometer shelter that contains the thermograph, are adopted as the fundamental basis. The difference between these standard temperatures and the readings of the thermograph sheet gives the thermograph corrections for 8 a. m. and 8 p. m. The corrections for all other hours are obtained by simple interpolation, and the values thus corrected are entered in the appropriate column of a form on which the monthly means for each hour are computed, as given in Part II.

The monthly extremes, published in Part III, are as given by standard self-registering maximum and minimum thermometers.

The monthly mean temperatures in Part II are the simple arithmetical means of the twenty-four hourly readings (from midnight, Eastern time, to 23 hours) without reduction to the middle of the day.

It is very possible that the records given by the Richard thermograph may be subject to systematic sources of error that are not wholly eliminated by the above-described simple checks and interpolations; especially are the extreme thermograph readings liable to show systematic differences from the self-registering maximum and minimum thermometers. It will, however, generally be found that the differences are not larger than the inherent imperfections of the two methods of recording temperatures. As stated in another place the uncertainties of temperatures given by maximum thermometers, as used by the Weather Bureau, are about one-half degree Fahr. and those of the minimum temperatures still larger. The uncertainty of the thermograph, as compared with the whirled thermometer, is fully 1° Fahr., to which must be added the uncertainties arising from the neglect of 0.3° Fahr. in the thermometer corrections and the error introduced by the shelter itself, as is also explained above in paragraph 3. The uncertainties of these hourly temperature readings are appreciably increased by the influence of the irregularities of the clocks that drive the record sheets.

(9) *Voluntary stations.*—Of the voluntary observers whose records are given in Part IV, probably one-half have standard thermometers furnished by the Weather Bureau or the respective State weather services; but very few have standard shelters or exposures, and the hours of observations are quite varied. The mean monthly and annual temperatures, as here published, have been deduced from the hours of observation adopted by the observer without correction for diurnal variation, except in a few cases where the simple means could not possibly give an approximate daily mean.

(10) *Daily mean temperatures.*—The monthly mean daily temperatures, given in Part III, are the averages of the daily mean temperatures without attempting to correct for the influence of any date that may be missing, and in general there has been no reduction to the mean of the normal month or year, so that the following monthly and annual means refer to the current calendar months and years. These daily mean temperatures are themselves the mean of the daily maximum and minimum without applying any reduction to the mean of 24 hourly observations. A similar daily mean temperature might be computed from the average of the observations at 8 a. m. and 8 p. m. standard time, but this has not been done. A correction for diurnal variation is necessary in either of these cases, the value of which may be approximately deduced from the work of Mr. McAdie; but such has not been applied in this volume. For the territory covered by the Weather Bureau stations, the mean of the four observations here given (at 8 a. m., 8 p. m., maximum and minimum) represents the daily mean temperature with an accuracy that is within the range of probable errors introduced by peculiarities of exposures, observers, and neglected thermometer corrections.

(11) *Frequency of high and low temperatures.*—The number of days on which the maximum temperature fell below 32° and the number on which it rose above 90°, also the number of days on which the minimum temperature fell below 32°, are given for each month in Part III.

(12) *Reduction to sea level.*—In drawing isothermal lines it is necessary that mean temperatures should be reduced to a homogeneous system as to exposure and location; among the reductions thus required the most important is generally conceded to be the reduction to a uniform altitude or to sea level. This reduction becomes an obscure and complex problem when we have to deal with the varied surface of the whole United States: Some attempts to devise philosophical systems of reduction have been made by Messrs. Upton and Ferrel in connection with the cognate problem of the reduction of the barometer to sea level. It is considered that the object of the present publication is to present only the original data for use in such problems as may interest the reader, consequently no attempt has been made to reduce either pressure or temperature to sea level. The comparison made by Prof. Ferrel between the mean monthly temperatures at high and low stations in the United States (see Annual Report of the Chief Signal Officer, 1886, appendix 23), seems to show that a diminution of one degree Fahr. for each 600 feet of altitude leads to a homogeneous system of isobars for each month, as well as for the year; this rate may therefore be provisionally adopted for studies in the mechanics of the atmosphere, but in local climatological studies no such reduction is necessary.

PRESSURE.

(13) *Barometric standard.*—On several occasions before 1881 there were imported by Gen. A. J. Myer copies of the substandard barometer manufactured by Adie & Sons, of London, with accompanying "Kew" certificates; these were compared among themselves and with the barometers that had been temporarily used as substandards, as furnished by James and H. J. Green, of New York, and by the Surgeon-General of the Army, and it was concluded that the system of corrections adopted in 1870 had effected a fair agreement between the English and American standards.

In 1883 Prof. Frank Waldo made a careful comparison between the standards used by various meteorological services in Europe and America, from which it may be concluded that the barometric standard then used by the Signal Service was about 0.007 of an inch above Wild's normal at St. Petersburg and about 0.003 above Welsh's normal at Kew, but about 0.001 below the Marek normal (I) at the International Bureau of Weights and Measures at Paris. Similar comparisons, by Chistoni in 1881, Sundell in 1886, and Brunnow in 1887, show that these international comparisons of normal barometers have not yet been executed with sufficient accuracy to insure against an uncertainty of plus or minus 0.002 inch in the result. We may therefore conclude that in 1883 the ideal standard of the Weather Bureau agreed with that of the "International Bureau of Weights and Measures," which is now adopted as the recognized authority for all meteorologists. The actual barometers then used, as representing the ideal standard, are still preserved in the Weather Bureau, and numerous intercomparisons among them, as well as comparisons with new instruments constructed as normals of independent character, seem to assure that no change has yet taken place in our barometric standard greater than plus or minus 0.003, which limit includes the influence of the adopted reduction of the mercurial thermometer to the standard air thermometer. Our knowledge of this whole subject is, however, not entirely satisfactory.

(14) *Station barometers.*—The barometer used at Weather Bureau stations for personal observations is the ordinary portable mercurial open cistern; it is kept in a glass case for better preservation against dust and accident and changes of instrumental temperature. Each observation requires an adjustment of the zero point and of the upper vernier, together with a reading of the attached thermometer. Such mercurial barometers are called substandards when the tube and cistern are large and the instrument is regarded as a permanent fixture. The station barometers have been compared with the substandard at Washington before being issued to the stations, and each has a correction card showing both the corrections to the attached thermometer and the so-called correction for instrumental error. This latter is determined in the instrument

room of the Washington office and at the ordinary atmospheric pressures and temperatures, and usually by the same person. It represents the average total influence of any remnant of air in the vacuum chamber, of capillarity, of verticality, of errors in the attached thermometer or in the graduation of the barometer scale, of the observer's peculiarities, and especially of the difference in temperature between the mercury, the scale, and the attached thermometer. None of these sources of error are likely to continue unchanged when the barometer is removed to a distant station; therefore reasonable doubt may exist as to how far the "correction for instrumental error," which is really a reduction to the ideal standard of pressure, applies to the instrument in its new location. By means of similar portable barometers in the hands of inspectors, the relation of the barometers, at the stations, to the standard at Washington is frequently checked, but here again sources of error exist, and unless such inspections are performed by skilled observers it is considered preferable to send a new barometer to any station whose instrument is apparently out of order.

(15) *Barometer corrections and reductions.*—Experience has shown that it is impracticable to secure an agreement to within 0.001 of an inch between the standard and the station barometers by any system of comparisons and corrections, such as was formerly attempted; therefore, since 1889 the rule has been adopted of omitting all consideration of the instrumental error when that is only 0.006 of an inch or less. Corrections that are larger than this are, however, properly made, as also the ordinary corrections for the temperature of the attached thermometer. This latter correction becomes quite uncertain when the temperature of the barometer is rapidly changing, errors of 5 degrees of temperature or 0.013 inch of barometric pressure being quite possible; therefore, although both these corrections are applied as given to the nearest 0.001 inch, still the resulting pressure is published only to the nearest hundredth of an inch. If the deterioration of the station barometer becomes appreciable at any time, as shown by comparisons with an inspector's or the extra station barometer, then a new value of the "instrumental correction" is determined and authorized to be used.

(16) *Reduction to sea level.*—The daily telegraphic reports give the barometric pressure as further reduced to sea level; these are charted on the morning and evening maps daily at Washington and serve, by their agreement with each other, to detect the occurrence of any accidental change in any station barometer. There is good reason to believe that except for the effect introduced by the variation of gravity, our entire system of barometric pressures is consistent to within 0.01 or 0.02 inch with those made with the standard barometer at Washington; the only room for serious doubt occurs in the case of very high or very distant stations.

(17) *Reduction to standard gravity.*—In order to reduce pressures measured by the mercurial barometer to the standard ordinarily used for such measurements of pressure, a correction is still required for the influence of the variation of gravity upon the mercurial barometer. This rather large correction is nearly constant for a given station and is easily combined with the other reductions to standard. The use of this reduction was given up in 1888, and therefore in the present volume it has not been applied, although, on the other hand, its value is given at the head of the table for each station in Parts II and III, so that the reader can apply it as there directed.

(18) *Corrections for local wind effect.*—As the pressure within the room of the observing station only agrees with the pressure of the free air outside when no appreciable wind is blowing, it has been a question as to whether observations made during high winds should be corrected for such wind influence or should be rejected altogether; the latter policy has been adopted at the Ben Nevis station and the former has been suggested as a possible alternative; but neither method has been adopted by the Weather Bureau. Fortunately some observations which have been made on Mount Washington would seem to show that the wind effect on the barometer at that station, as the building stood in 1886, was only about one-third of the maximum possible. In the absence of similar studies for other stations it may be assumed that the same rule is approximately true for them also, viz, that when any wind is blowing the pressure within the observing room may be higher than that in the free air outside by an amount equal to one-third, or it may be lower by an amount equal to one-tenth of the maximum effect given in the following table:

Wind velocity.	Maximum wind effect.
Miles per hour.	*Barometric inch.*
20	0.015
40	0.061
60	0.138
80	0.245
100	0.383
120	0.548

A simple method of mounting the barometer so as to entirely avoid this annoying local wind effect has been devised, but its introduction into use at stations has not yet been decided on.

(19) *Personal observations.*—The observations whose means are given in Part III are those made by the observer personally at each station at 8 a. m. and 8 p. m., standard time, as corrected only for "instrumental errors" and temperature of attached thermometer; their mean values relate to the altitude of the barometer above sea level, as given at the top of each table. They receive a further "reduction to sea level" for use in the daily weather maps, but the method of reduction is especially adapted to the special needs of the daily telegraphic service rather than to climatic studies; wherefore the reduced observations are not given in this volume.

(20) *Hourly barograph readings.*—The hourly records, whose means are given in Part II, are taken from the self-registering instruments. The barograph in use at the Washington station is known as Foreman's barograph and consists substantially of a siphon barometer and an electrical recording apparatus that communicates the motion of a float in the short leg of the siphon to a pen which traces the record on the revolving cylinders driven by clockwork. Two cylinders are operated in connection with this instrument, one making a complete revolution in twenty-four hours and the other in fifteen days. The barometric changes are magnified four times. The daily record sheet, from which the published readings have been obtained, has quite an open time scale, a movement of about eleven-sixteenths of an inch corresponding to an hour of time. The horizontal rulings on the sheet are almost one-tenth of an inch apart, each vertical space representing .02 of an inch of pressure. The effect of temperature upon this siphon barograph is very complex, and its magnitude is not easily determined *a priori;* by keeping the instrument in a room of comparatively uniform temperature, it is presumed that the instrumental errors have been kept correspondingly steady; the record sheets for this barograph are changed daily at noon, standard time, which is eight minutes faster than Washington local time; at the same time a personal reading of a substandard mercurial barometer is made, and, after proper reduction for temperature and instrumental error, is entered on the margin of the sheet; the new sheet is so adjusted that the pen takes up the new record at the point corresponding to this corrected reading, so that the barograph trace is always a very close presentation of the local atmospheric pressure.

The Foreman barograph is located some 20 or 30 feet below the so-called station barometer, and its records, therefore, require a minus correction in order to reduce them to the local or station pressure. The sum of this and of all other corrections that the barograph trace may require is determined by the process that is employed in filling up the monthly sheet of hourly pressures, as deduced from barograph readings, which process is as follows:

The readings of the mercurial barometer in the station room, as made by the regular observer personally at 8 a. m. and at 8 p. m., seventy-fifth meridian time, having been corrected for temperature and instrumental error, are entered in the columns for those hours respectively, as being the standard to which all barograph readings must be reduced. The barograph readings for those same hours are then compared with these standards and the corresponding corrections required to be added to the barograph readings at those hours in order to reduce them to standard pressure are entered in red ink alongside the figures in the 8 a. m. and 8 p. m. columns. If these corrections agree for any two consecutive standard pressures, it is assumed that the intermediate readings of the barograph require the same correction; if they differ, then the corrections for the intermediate hours are found by using a very simple device for interpolation. These corrections generally amount to only a few hundreths of an inch and are applied mentally to the hourly

readings of the barograph traces, which corrected readings are then entered in the monthly table of hourly readings. The figures in these tables are given to the hundredths of an inch; they are affected by several sources of error, namely: (1) The error of personal readings, as explained above. (2) The errors of reading from the barograph sheets. (3) Any systematic error in the barograph curves that is not eliminated by the comparison at 8 a. m. and 8 p. m. These generally vary with the temperature and pressure and irregularities in time scale. Apparently the sum total of these uncertainties, and for rapidly changing pressure, may amount to 0.05 of an inch, but the probable error of the data here published is about 0.02.

The further correction for reduction to standard gravity has not been applied, but is given at the head of each table.

The reduction to sea level is not applied, as being inappropriate to local climatic data; it is described in connection with the publication and use of daily weather charts.

The barographs used at all other stations except Washington are the self-registering aneroids constructed by Richard Bros., Paris. The scale of the record is such that 0.01 inch barometric pressure is represented by 0.01 inch on the record sheet; the time scale is such that 0.01 inch on the record corresponds to 9 minutes of time. The uncertainty of a pressure, as read off from the sheet, is probably more than 0.01 inch, and the probable error of the data here published is greater than that of the data taken from the Washington barograph.

The Richard barograph is imperfectly compensated, mechanically, for the effect of the temperature of the instrument; on the other hand, the apparatus is kept in a room of fairly uniform temperature and the errors due to temperature variations are partially allowed for by the daily reduction to 8 a. m. and 8 p. m. standard observations. The register sheets are renewed weekly, at noon Monday; the hourly readings and the reduction to the personal observations at 8 a. m. and 8 p. m. are made precisely as in the case of the Foreman mercurial barometer at Washington.

(21) *Extremes of pressure.*—The averages of the maximum and minimum values of barometric pressure, as given in Part II, have been computed from the daily extremes; the latter were selected from among the hourly readings and do not refer to any extremes that may have occurred between those readings. The extreme pressures that are given in Part III are selections from the personal readings made at 8 a. m. and 8 p. m., or occasional possible intermediate values. It is therefore quite possible that higher maxima may have occurred at about 10 a. m. local time at our western stations, or lower minima at 3 p. m. local time, especially at our western stations, since these are the approximate hours of the diurnal maximum and minimum.

(22) *Normal mean pressures.*—No corrections have been applied to the daily means of twenty-four observations, or to the monthly means of calendar number of days, or to the annual means of twelve months, in order to reduce them approximately to the central point of the respective normal periods; those who desire to apply such corrections will compute them by the methods introduced by De Forrest and Kleiber; such reductions will be of importance only in dealing with normals based on many years of observations, and it is not considered proper to apply them to these annual means.

MOISTURE OF THE AIR.

(23) *Methods.*—The whirled psychrometer was adopted by the Weather Bureau in 1886. As before stated, this psychrometer is whirled inside of the light wooden thermometer shelter, and therefore gives the average condition of the air within it. The adopted rate of whirling is such that the air flows past the thermometer bulbs at the rate of from 10 to 25 feet, or from 3 to 8 meters per second.

(24) *Tables.*—The physical theory and the corresponding numerical tables by means of which the amount of atmospheric moisture is computed from the readings of the whirled psychrometer are those devised by Ferrel, as given in the Annual Report, Chief Signal Officer, 1886, Appendix 24, except only that a revision of the tables has been made to accord with Marvin's revised values of the tension of aqueous vapor at low temperatures. The newer tables, thus revised, are given in "Instructions to Voluntary Observers of the Weather Bureau," by Thomas Russell, Washington, 1892.

In using these tables, that one which gives the influence on the psychrometer of the prevailing barometric pressure, namely, Table III, page 91, "Instructions to Voluntary Observers" of 1892, has generally been neglected, and is at present only considered when an observer at a very high station computes special tables for his own station from the general tables given by Ferrel and Russell. This correction for barometric pressure was adopted in 1882, but discontinued in 1888. At present it is intended to be neglected only when it seems to be smaller than errors arising from other sources, and in so far as it is neglected the vapor pressure, dew-point, and relative humidity for high stations, as computed by tables appropriate for low stations, are all too small by quantities that may sometimes be as large as 0.05 inch, 15° F., and 50 per cent, respectively.

Both the dry- and wet-bulb and dew-point temperatures should be reduced by proper corrections to the adopted thermometric standard, namely, the normal air thermometer; but the observed dew-point unreduced has been accepted by meteorologists as the standard determination of the atmospheric moisture, and the psychrometric tables of Regnault and Ferrel are simply used to enable us to deduce from the psychrometer that which would have been observed on the dew-point apparatus if that had been used. The correction to the observed dew-point in order to convert it into standard degrees often amounts to half a degree F., and the correction to the corresponding wet bulb or to the depression of the wet bulb is somewhat less.

In order to obtain the temperature of the dew-point within 1° F., the difference between the wet and dry bulbs should be correctly given to within 0.1° F. This necessitates correcting every observed temperature for all sources of error to which mercurial thermometers are liable in order to obtain the equivalent indications of the standard thermometer; but, as has been before stated, this is not now attempted.

(25) *Accuracy of observed values.*—Since the corrections just explained are neglected there is, therefore, a corresponding uncertainty in individual dew-points of 1° or 2° at high temperatures, increasing up to a possible 5° or 10° at zero Fahrenheit, and a possible 10° or 20° at the lowest temperatures. The uncertainty of the monthly mean dew-point will, however, scarcely reach 3° F. in winter or 1° in summer; the corresponding uncertainty of the monthly means of observed vapor pressure is 0.03 inch in summer and 0.01 in winter, and the uncertainty of the monthly means of observed relative humidity will be about 2 per cent in summer and 10 per cent in winter. These ranges of uncertainty can not be materially diminished except by simultaneously changing both the style of the thermometer-shelter, the psychrometric tables, and the method of dealing with small corrections to the thermometers. The accuracy at present attained is confessedly below the demands of special laboratory studies, but compares fairly well with the irregularities of local atmospheric temperatures and moisture, with the accuracy of weather predictions, with the demands of international climatic studies, and with our present theoretical knowledge of meteorology.

(26) *Accuracy of mean values.*—The monthly means of observed dew-points (but not of *observed* vapor pressures and relative humidities) are given in Part III for 8 a. m. and 8 p. m. As pressure and humidity are not simple linear functions of the dew-point, therefore the monthly means of the observed pressures and humidities will not rigorously correspond to the monthly mean of the dew-points, therefore in Part III the mean vapor pressures and relative humidities are given as computed directly from the mean temperatures of the dew-point and the air; the pressures thus computed from the mean dew-points are somewhat lower than if the means of original daily obsevations had been given.

The diurnal variation in the moisture of the air is not known with sufficient accuracy to justify computing mean daily values (and corresponding monthly means) from the psychrometric observations made at 8 a. m. and 8 p. m.; therefore such normal values are omitted

WINDS.

(27) *Self-registers.*—The velocity of the wind is recorded at all Weather Bureau stations; the direction and velocity are recorded at about one-third of the stations on what is known as the "double register," which is, however, now being replaced in some cases by a "triple register" in order to provide for recording the rainfall, the sunshine, or some other meteorological element. The records from 28 of the stations that are furnished with double or triple registers will be found in

Part II. On these instruments the direction of the wind is recorded every five minutes to the nearest one of the eight principal points of the compass; the record is made by the impression of type letters, N. S. E. W., so that the wind direction is read off from the register without further trouble. The horizontal movement of the air is given by the ordinary Robinson cup anemometer, constructed on the assumption that the cups move one-third as fast as the wind; each mile of wind motion is recorded by a dash on the register simultaneous with the completion of the electric contacts within the anemometer. The hourly movements, whose averages are given in Part II, are obtained by counting the number of dashes recorded each hour upon the register. The numbers represent the total record for the hour ending at the time that is given at the head of the column. No corrections have been applied to convert the anemometer records into true velocities; neither have any been applied to correct for orographical peculiarities of location.

The summary of wind directions, as given in Part II, include only those that were recorded most frequently during the hour.

Accuracy.—The anemometers are all compared at Washington before being issued to stations. They are oiled frequently, and at each station a spare instrument, that is kept in good condition, is occasionally compared with the one in constant use. The records of these comparisons show that so far as the instruments are concerned the registered horizontal movement of the air is within 2 per cent of what would be given by a normal Robinson anemometer. Those who desire to reduce the data here published into standard miles, namely, to correct for the peculiarities of the Robinson anemometer, should make use of the results of Prof. Marvin's investigations (see Ann. Rep. C. S. O., 1890, p. 693), according to which the true velocity (V) may be computed from the Robinsonian velocity, or the simple reading (D) of the anemometer dial, by the formula

$$\log. V = 0.079 + 0.9012 \log. D,$$

or it may be taken from the following table:

Velocities.		Velocities.	
By Robinson anemometer dial.	True velocity.	By Robinson anemometer dial.	True velocity.
M. p. h.	*M. p. h.*	*M. p. h.*	*M. p. h.*
5	5.1	35	29.6
10	9.6	40	33.3
15	13.8	45	37.1
20	17.8	50	40.8
25	21.8	55	44.4
30	25.7	60	48.0

SUNSHINE AND CLOUDINESS.

(28) *Sunshine recorder.*—Continuous records of sunshine have been obtained by an apparatus known as the "Weather Bureau Photographic Sunshine Recorder," which may be described as Marvin's modification of Jordan's Sunshine Recorder. The record sheets, after the proper photographic development, show a continuous line corresponding to steady sunshine, with blank spaces corresponding to cloudy obscuration. The percentage of continuous line included between each calendar hour of standard time is read off by the observer and given in Part VI as sunshine; the difference between this number and unity represents cloudiness; the time scale is such that one hour occupies a half inch on the form. The apparatus is sufficiently sensitive to make a record of sunshine when the sun is about half an hour high on an ordinary cloudless day. A faint trace is made on hazy days even with the sun in the meridian; the absence of sunshine, as recorded by this apparatus, corresponds to the presence of a layer of air or haze or cloud, sufficiently thick to so reduce the direct light of the sun that its disk is not distinguishable from the region surrounding it.

(29) *Cloudiness.*—The cloudiness recorded in Part III is derived from personal observations. The proportion of sky covered by clouds is estimated by the observer at 8 a. m. and 8 p. m. standard

time and recorded on the scale of 0 to 10. The two simultaneous observations can not be combined into a normal daily mean in the present state of our knowledge of the diurnal variation in cloudiness, and are therefore given separately in Part III. In order, however, to obtain a general record of the sunshine as affecting the growth of plants, the observer keeps some memoranda of the cloudiness, sufficient to enable him at the end of the day to assign a percentage representing the average condition of the sky from sunrise to sunset; the resulting average for each month is given in Part III in the column of "cloudiness during daylight."

The number of days that are clear, as given in Part III, includes those on which the daylight cloudiness has been 0, 1, 2, or 3 tenths; the days partly cloudy are those on which the daylight cloudiness has been 4, 5, 6, or 7 tenths; the cloudy days are those having 8, 9, or 10 tenths of cloudiness during daylight.

EVAPORATION.

(30) *The Piche evaporometer.*—The Piche evaporometer has been used at numerous Weather Bureau stations. It may be considered as an instrument for determining the average hygrometric condition of the atmosphere during any interval of time and can only give a crude idea of the actual evaporation from the natural surfaces of land and water. Owing to the want of space these records are not given in the present volume.

PRECIPITATION.

(31) *Rain gauges.*—The rain gauges, almost universally used at the regular Weather Bureau stations, have a circular catchment area of about 8 inches diameter, and the snow, hail, or sleet caught within them is melted and measured as water. The rain gauge proper is set within an inclosing cylinder of 8 inches diameter and 2 feet high, which serves as an overflow attachment in the case of heavy rains and as a snow gauge in the winter season. The gauges used by the voluntary observers represent a large variety of patterns. The discrepancies introduced by this variety of patterns are believed to be inappreciable in comparison with the variations due to location and wind.

On account of the location of the regular stations of this service in large cities the gauges whose readings are given in Part III are usually placed on the roofs of large buildings, but the records for voluntary stations, as given in Part V, are derived from gauges that are generally near the ground and in open fields.

(32) *Times of observations.*—The sum total of the depth of rain and melted snow is measured to within 0.01 inch, not only at the end of every shower, but also at 8 a. m. and 8 p. m. standard time daily. By adding these two regular observations we obtain the total precipitation for the 24 hours preceding 8 p. m. of the civil day to which it is accredited.

(33) *Accuracy.*—The snow caught and retained in the gauge is melted and measured as water. No correction is applied for the snow that is lost out of the gauge by the eddying action of the wind; consequently in some cases the record is less than would be given if the observer had measured cylinders of snow cut from the spots representing the average snowfall on the ground. The loss of both rain and snow caused by high winds is undoubtedly larger at the regular telegraph stations of the Weather Bureau than is the case at the voluntary stations whose gauges are located in the open country and near the ground, but this loss does not appear to be so large as to make the monthly and annual sums derived from these two classes of gauges wholly inconsistent with each other; on the contrary, except at a few stations, the differences between the annual rainfall at city and country gauges are not larger than is plausibly due to actual differences in the geographical distribution of rain.

By the maximum precipitation in twenty-four hours, given in Part III, is meant the actual measurements for any twenty-four hours; it does not refer to the rate of rainfall for twenty-four hours, as deduced from short heavy showers.

The number of days with precipitation amounting to 0.01 and 0.04 inch, respectively, relates to the rainfall from 8 p. m. to 8 p. m. and not from midnight to midnight.

The number of days with snow includes all those on which at least 0.01 inch of melted snow, corresponding to about one-tenth of an inch of unmelted snow, has fallen in the twenty-four hours preceding 8 p. m.

The number of days with hail includes all those on which at least a trace of hail fell.

No record of amounts of dew is given.

The number of days of fog includes all those on which fog prevailed for at least an hour and was dense enough to obscure objects a thousand feet distant.

REPORT OF THE CHIEF OF THE WEATHER BUREAU.

PART II.

HOURLY AVERAGES OF ATMOSPHERIC PRESSURE, TEMPERATURE, AND WIND FROM THE RECORDS OF SELF-RECORDING INSTRUMENTS AT TWENTY-EIGHT STATIONS,

1891-'92.

Pressure.—The values for 8 a. m. and 8. p. m. are those of the station mercurial barometer; all other hourly values have been obtained as described on page 43. The means of the maxima and minima pressures given on the extreme right of the tables have been computed from the daily extremes. The latter were selected from among the twenty-four hourly readings, and do not include, therefore, maxima and minima values that may have occurred between the hourly readings.

Temperature.—The averages for each hour of the day, except 8 a. m. and 8 p. m., have been obtained from the thermograph record as described on page 40. The 8 a. m. and 8 p. m. averages are those of the station dry thermometer. The means of maxima and minima temperatures have been derived from readings of standard self-registering thermometers.

Wind.—The average velocity for each hour of the day, as given in the tables, is the simple arithmetical mean of the velocities for the hours ending with those printed at the head of the table. The maximum velocity is for a five-minute period. No corrections to reduce to true velocities have been applied. A summary of wind direction is given on the right of the tables of average velocity. The entries under the several headings, "N.," "NE.," etc., represent the number of *hours* during the month that the prevailing direction of the wind was from the point indicated by the heading. The direction of the wind is registered every five minutes, but only the direction that prevailed during the hour has been given.

References: H=Height of barometer above sea level.
h_t=Height of thermometer above ground.
h_a=Height of anemometer above ground.

The inches have been omitted in the pressure tables except for January; the reader will have no difficulty in supplying the proper values for the remaining months.

AVERAGE PRESSURE, IN INCHES AND HUNDREDTHS, FOR EACH HOUR OF SEVENTY-FIFTH MERIDIAN TIME.

REPORT OF THE CHIEF OF THE WEATHER BUREAU.

PART III.

MONTHLY AND ANNUAL METEOROLOGICAL SUMMARIES FOR WEATHER BUREAU STATIONS.

1891-'92.

A detailed account of the instrumental equipment of observing stations, the corrections applied to the various readings, and finally the probable accuracy of the results will be found in the article by Professor Cleveland Abbe, page 37; some of the leading features in regard to the reduction of observations are repeated here, however, for convenience of reference.

Pressure.—The monthly means and extremes of pressure have been reduced to 32° Fahrenheit, and corrected for instrumental error when the value of the latter correction is more than $\pm$ .006 of an inch.

Temperature.—The monthly means have been obtained by the formula $\frac{\text{max.} + \text{min.}}{2}$. The extremes are for the civil day, midnight to midnight.

Moisture.—The monthly mean vapor pressure has been obtained directly from the monthly mean temperature of the dew-point. The relative humidity and the dew-point have been obtained from the individual values for 8 a. m. and 8 p. m.

The maximum precipitation in 24 hours is for any period of 24 hours. The daylight cloudiness is the average of a number of personal estimates made during the day.

Wind.—The average hourly velocity is the total wind travel divided by the number of hours in the month. Maximum velocities are for a 5-minute period. A wind velocity of 40 miles per hour is considered as a gale.

The word "Calm" appears in the column headed "Prevailing direction" whenever the number of "Calms" observed has been greater than any direction.

Number of days.—The designation of a day with no clouds or less than three-tenths cloudiness has been changed from "Cloudless," heretofore used, to "Clear."

Time.—Eastern time (75th meridian) is the standard used in all of the observation and map work of the Weather Bureau.

References and abbreviations.—H = Height of barometer cistern above mean sea level; h_t. = height of thermometer above ground; h_r. = height of rain-gauge above ground; h_a. = height of anemometer above ground.

ANNUAL METEOROLOGICAL SUMMARY FOR THE YEAR ENDING DECEMBER 31, 1891.

ANNUAL METEOROLOGICAL SUMMARY FOR THE YEAR ENDING DECEMBER 31, 1891—Continued.

FRESNO, CAL.

[H=338 feet; h_t=78 feet; h_r=66 feet; h_a=77 feet.]

Month.	Wind. By self-registers. Average hourly velocity.	Prevailing direction. *a*	Maximum velocity.	Direction at time of maximum velocity.	Number of days with gales.	Number of winds, 8 a. m. and 8 p. m. North.	Northeast.	East.	Southeast.	South.	Southwest.	West.	Northwest.	Calm.	Number of days. Clear.	Partly cloudy.	Cloudy.	Precipitation. .01 inch and over.	.04 inch and over.	Snow.	Hail.	Fog.	Maximum temp. Below 32°.	Above 90°.	Minimum temperature below 32°.	Electricity. Thunderstorms.	Auroras.

a By eye observations, 8 a. m. and 8 p. m. when there is no self-register at station.
b During all months, except June and December, "Calms" (winds of 4 miles per hour or less) were reported more frequently than directions.
c From 8 a. m. and 8 p. m. observations. *d* For 27½ days. *e* For 27 days. *f* For 17 days.

ANNUAL METEOROLOGICAL SUMMARY FOR THE YEAR ENDING DECEMBER 31, 1891—Continued.

a By eye observations at 8 a. m. and 8 p. m. when there is no self-register at station.

REPORT OF THE CHIEF OF THE WEATHER BUREAU.

PART IV.

MONTHLY AND ANNUAL MEAN TEMPERATURE AND ANNUAL EXTREMES OF TEMPERATURE, TOGETHER WITH THE DATES OF FIRST AND LAST KILLING FROST, 1891–'92.

The monthly and annual averages given in the following tables are taken largely from the records of voluntary (unpaid) observers. The paid stations of the Weather Bureau are indicated by an asterisk (*). The records of voluntary observers are given as made; no attemp has been made to reduce them to a homogeneous system. About half of the voluntary observers have standard instruments, but very few have what may be called standard shelters. The hours of observation at the regular stations of the Weather Bureau have already been described; the observing hours at voluntary stations vary greatly. The letters "*a*," "*b*," etc., following the name of a station have the following significance:

a = mean temperature computed by the formula $\frac{1}{4}$ (7+2+9+9).
b = mean temperature computed by the formula $\frac{1}{2}$ (8+8).
c = mean temperature computed by the formula $\frac{1}{2}$ (7+7).
d = mean temperature computed by the formula $\frac{1}{2}$ (6+6).
e = mean temperature computed by the formula $\frac{1}{2}$ (7+2).
f = from various hours reduced to true mean by special table.
g = mean temperature computed by the formula $\frac{1}{3}$ (7+2+9). (Southern Pacific Railway.)

The absence of a letter indicates that the mean has been made as follows: $\frac{\text{Mean max.} + \text{mean min.}}{2}$

The small Roman letters in the body of the tables indicate the number of days missing from the records, thus "c" indicates 3 days missing, etc.

The last date of killing frost in spring and the first occurrence of a killing frost in autumn are given at the right of the table. Many observers, however, do not report dates of frost, and still others do not distinguish between light and killing frost. The date of the first and the last occurrence of a minimum temperature of 32° has been used in all cases where no frost reports were made. Data for stations so entered have been distinguished from regular frost reports by a dagger (†).

Bracketted values have been supplied by interpolation.

[1] Weather Bureau. [2] J. S. Meyer.

REPORT OF THE CHIEF OF THE WEATHER BUREAU.

PART V.

MONTHLY AND ANNUAL PRECIPITATION.

ALL STATIONS.—1891-'92.

The precipitation values given in the following tables have been taken largely from the records of voluntary (unpaid) observers. The paid stations of the Weather Bureau have been indicated by an asterisk (*). Probably two-thirds of the voluntary observers have standard rain gauges, the remainder having gauges similar in pattern to the standard, or, in a few cases, improvised gauges of their own construction.

The bracketed values have been obtained by a comparison of the data for adjacent stations and are to be considered only as an approximation to the true amount.

When two or more observers reside in the same city the reports of all are given. Foot-notes distinguish between the respective observers. The discrepancies between the amounts recorded by the separate observers are often considerable; in general they are due to differences in exposure, although at times one observer may make the last measurement of the month at 6 o'clock p. m., whereas another observer may defer it to 9 p. m., thus causing a difference in the amounts recorded on the last day of the month.

MONTHLY AND ANNUAL PRECIPITATION (IN INCHES AND HUNDREDTHS) FOR 1891, COMPILED FROM THE REPORTS OF OBSERVERS OF ALL CLASSES, 1891.

[1] Rainfall observer. [2] Dr. F. R. Zeit. [3] J. S. Meyer. [4] Weather Bureau.

REPORT OF THE CHIEF OF THE WEATHER BUREAU.

PART VI.

MISCELLANEOUS METEOROLOGICAL TABLES AND REPORTS.

Normal Pressure, Temperature, and Precipitation (monthly); Snowfall, 1891–'92; Sunshine, 1891–'92; Rivers and Floods; Destructive Wind Storms; Casualties by Lightning; Movement of areas of high and low barometric pressure, 1891–'92; Balloon voyage; Relations of solar magnetism to terrestrial magnetism and meteorology; Condensation of atmospheric moisture.

1891-'92.

MONTHLY NORMALS OF PRESSURE, TEMPERATURE, AND PRECIPITATION.

ATMOSPHERIC PRESSURE.

Two sets of values are given for each station, actual or local pressures and sea-level pressures. The first set or upper horizontal row was obtained by taking the arithmetical average of the mercurial barometer readings, corrected for temperature and instrumental error, from January 1, 1873, to December 31, 1892, after first reducing the readings at each station to the elevation given in the table which is that of December 31, 1892. At stations established subsequent to January 1, 1873 (Table I, p. 11), the number of years of record used is of course correspondingly shorter. In a few cases where a station has been moved from one town to another, not many miles distant, the records of the first station have been reduced to the elevation of the later station.

The second horizontal row contains the sea-level pressures. The reductions were made after the method described in Professional Paper No. VI of the Signal Service.

The elevations have been determined mostly from the precise levels of the U. S. Coast and Geodetic Survey, or from railroad levels that have been connected with some line of precise levels. At a very few stations the elevation has been determined by the barometer.

TEMPERATURE.

The normal temperature formerly used was made up from observations taken three times a day. Since July, 1888, however, the mean temperature has been calculated from the daily extremes. The latter method is not altogether satisfactory, but it is perhaps the best that can be adapted to the varied needs of the Bureau.

Examination has shown that mean temperatures, derived from daily extremes, may differ as much as 1.5°, and in extreme cases almost 2° from the true mean, but on the average the difference is about 0.5° F., being less in summer than in winter, although the reverse obtains in some localities.

The use of self-registering maximum and minimum thermometers did not become general until 1873, although a few stations began to use them in 1872. The number of years' record used in computing the normals is given at the right of the table. The period covered is from 1872–'73 to 1891, inclusive.

PRECIPITATION.

The values given are the simple arithmetical means of the monthly amounts of precipitation recorded at Weather Bureau stations from the beginning of observations—November 1, 1870—to December 31, 1891, inclusive, except at Jupiter, Fla., and Rapid City, S. Dak., where the year 1892 has been added.

Signal Service and Weather Bureau records of precipitation have been combined with reliable voluntary records wherever the number of years given at the right of the table exceeds 22.

The elevation of the rain gauge above ground, given in the table, is that of January 1, 1891. It is impracticable to give the several previous elevations of each gauge.

NORMAL AIR PRESSURE 1873 TO 1892.

[Sea-level pressures are given in the lower set of figures at each station.]

SNOWFALL OF THE UNITED STATES.

In the early years of the Signal Service snow was melted and then measured in the same manner as rain; no measurements were made of the depth of unmelted snow, however, and but little attention appears to have been given to the subject until the early part of 1883, when its importance was recognized by the issuance of General Orders No. 25, as follows:

* * * To determine the amount of snowfall, take the cylinder of the rain gauge (or the overflow attachment), invert it, and plunge it vertically into the *level* snow until it reaches either the ground or the upper surface of the snow that fell before the last preceding telegraphic observation; dig away the surrounding snow, slip a sheet of tin under the lower end of the cylinder, lift it up, and put the cylinder, open end upward, in a warm place where the snow will quickly melt; then measure the depth of the water. The actual depth of water in the cylinder will be recorded and reported. * * *

Special instructions will be given for measuring snowfall at stations where it cannot be done in the regular way. * * *

The instructions in force prior to the above date are silent as to the means to be adopted in ascertaining the amount of precipitation from snowfall. It may be said that, as a rule, observers melted the snow caught in the collector of the rain gauge and measured the resulting water in the same manner as rainfall, note being made, however, of the fact of its being melted snow. They were also authorized, in cases where it was impracticable to melt the snow, to record one-tenth of its depth as the equivalent in water of the unmelted snow.

Snow gauges (galvanized iron cylinders, 2 feet high and 8 inches in diameter) were first put into use in the fall of 1884, and observers were directed to measure the catch of unmelted snow and afterwards the depth of melted snow. No provision was made until December, 1887, for rejecting the catch of the gauge when the snow drifted badly. On the latter date authority was given in all cases where there was reason to believe that the snow gauge had not caught the entire fall of snow, to take the average depth on the level as the official record, using the same ratio as in the past—viz, 1 to 10 in determining the amount of precipitation that should be recorded. No departure from this ratio for different kinds of snow or for snow at different seasons of the year has ever been made.

In addition to the foregoing, an entirely independent series of measurements of the depth of snowfall for each twenty-four hours was instituted in the spring of 1884. The number of inches and tenths of inches of snow which fell during the twenty-four hours was determined as accurately as possible by measurements made at points where the snow appeared to be of average depth. From these data the table which follows was prepared. The table presents for the first time in the history of the meteorological service of the United States a record of the average distribution of snowfall, and also a record of the seasonal fall of 1891–92. The normals have been calculated for the seven years ending with May, 1891. They can not be considered, however, as being other than approximate values on account of the shortness of the record.

The use of the word "normal" to express the conditions which obtain at stations in the extreme southern portions of the country where snowfall is an *abnormal* feature may be misleading. The record at Galveston, for example, shows the normal for the year to be 1.1 inches, while

as a matter of fact snow has fallen but twice in that city from 1884 to 1891, the aggregate of both falls being 7½ inches.

Another preliminary to be noted in any study of the snowfall data here given, is the fact that the meteorological stations are, for the most part, in large cities and towns, and therefore represent the snowfall of the valley or plain as distinguished from the snowfall of the mountain or plateau country. There are also small errors of uncertain sign in the records of individual stations due to the peculiar environments of the stations, but considering the difficulties in the way of securing accurate measurements in large cities, the records here given agree remarkably well.

The region of greatest snowfall, according to the figures in the table, will be found in northern Michigan. It resembles somewhat a circle of about 200 miles radius, having Marquette, Mich., as its center, with an average annual fall of 132 inches. In the western, southwestern, and southern quadrants of the circle the fall diminishes rapidly towards the circumference, where it is about 60 inches. In the southeastern quadrant, however, it is almost 100 inches (Alpena, Mich.), diminishing rapidly from that depth to 40 inches at Port Huron, Mich. The decrease from northern Michigan southward is very rapid, being about an inch in every 4 miles between Chicago, Ill., and Marquette, Mich., and 1 inch in every 12 miles from Chicago to Cairo, Ill. The snowfall at points on the southwestern borders of lakes Michigan, Huron, and Erie is markedly deficient as compared with stations less than 100 miles distant to the north or northeast. The difference between the snowfall at Port Huron and Alpena, Mich., has already been mentioned. The difference between Cleveland, Ohio, and Erie, Pa., is 28 inches; between Erie and Buffalo, N. Y., 10 inches; Buffalo and Rochester, N. Y., 6 inches, and Rochester and Oswego, N. Y., 9 inches. The snow-bearing winds for these points are uniformly from some point intermediate between west and southeast, or generally over land surfaces; but with increase of latitude they take on more of a northerly component.

The average annual fall at stations on the Mississippi River varies from 1.8 inches at Vicksburg, Miss., to 37.4 inches at St. Paul, Minn., the greatest increase with latitude being between St. Louis, Mo., and Keokuk, Iowa, where it is slightly over 12 inches, or an inch in about 11 miles.

The snowfall of the plains west of the Mississippi River is generally less than for points of the same latitude on the river, but it increases as we approach the foot-hills of the Rocky Mountains and similarly the fall at upper Missouri River stations, as Bismarck and Fort Buford, N. Dak., is less than stations much farther south on the Mississippi River. The average annual fall for the greater portion of the Rocky Mountain region can not be given, even approximately. In regard to the fall of the middle latitudes of the United States it may be said that the line of 20 inches which enters on the east about midway between Washington, D. C., and Lynchburg, Va., divides the country as far west as Dodge City, Kans., into two almost equal parts. Below this line the snowfall diminishes quite rapidly, but does not wholly disappear, except along the Atlantic coast south of Charleston, S. C., southern Alabama and Louisiana, and the extreme southern portion of Texas. The Pacific coast from San Francisco to San Diego, Cal., is practically free from snow, and southern California and southern Arizona, as a whole, are also generally free from snow, except in the mountain regions. Probably the greatest snowfall in the United States of which we have a record, occurs on the mountain summits of eastern California and western Nevada. The record kept at Summit, Cal., on the Central Pacific Railway, elevation 7,017 feet, for the ten years ending with 1887, gives an average annual fall of 378 inches.

In 1891–1892, there was a general deficiency of snowfall in the North Pacific coast region and also to the eastward as far as central Montana. There was also an extensive area of deficient snowfall in the Upper Mississippi Valley and Upper Ohio Valley and the lake region extending from Pittsburg and Erie, Pa., on the east, to Concordia, Kans., Yankton, S. Dak., and Moorhead, Minn., on the west. Another and smaller area covered northern New England.

Perhaps the most remarkable features of the season's snowfall were the unusual storms of March 16–17, in western and central Tennessee, and of April and May in eastern Wyoming, northwestern Nebraska, and the southern portion of South Dakota. Snow began falling at 2:30 p. m., March 16, at Memphis, and continued falling till the morning of the 17th, when there was 18

inches of snow on the level—an unprecedented depth for this locality. Business was generally suspended and all ordinary means of transportation were completely disorganized.

The maximum depth of snowfall in twenty-four hours is given in the column on the extreme right. Of these 29 or 26 per cent occurred in March; 24 or 21 per cent occurred in December, and the remaining 60 were distributed as follows: 22 each in January and February; 8 in November; 7 in April, and 1 in May. The data are for the period 1884–1892, except at stations established subsequent to the first-named year. Table I, page 11, gives the dates at which observations began at all stations.

RIVER STAGES.

By Prof. THOMAS RUSSELL.

The systematic daily observation of river heights by Weather Bureau observers was begun in 1873 at a number of the more important places on the large rivers throughout the country. Previous to that time observations were made by the municipal authorities at a few places, Pittsburg, Cincinnati, Cairo, and St. Louis. Observations were also made at some places by the Engineer Corps, U. S. Army.

The observation of a river's height consists in noting the point reached by the water surface on a gauge made to indicate vertical heights in feet above the plane of low water. This vertical height is called the river stage. A river gauge is made of planks fastened to a bridge pier and marked to feet and tenths. Sometimes a gauge consists of a length of a pier about a foot wide dressed down to a smooth surface to hold the numbers and marks. Where there is no bridge pier available the gauge is made of timbers or blocks of stone laid along the incline of the river bank with a strip of iron on top for the marking. The marks are suitably placed along the incline to indicate vertical heights above low water.

In marking a river gauge the zero of the graduation is placed as nearly at the level of low water at the place as can be ascertained. When a gauge is once set it is not customary to change it without a very good reason, even if a stage of water should occur lower than the zero. Stages below the zero are indicated by the minus sign (—). Abnormally low water which may be sometimes due to an ice gorge above a place is not considered as a low water in establishing the zero of a gauge.

Information in regard to river stages from day to day is important to boating interests, especially at low stages of water, as indicating the depth of water available for boats in shallow parts of a channel.

When sudden rises to high water occur, observations of stages are of value in estimating probable rises at points farther down the stream. Warnings based on the reports of stages are sent by telegraph to places interested.

River stages at numerous points are telegraphed daily to places interested in the information. At some of the larger cities on important rivers where there are regular Weather Bureau stations, daily river bulletins are issued and the reports of stages are published in the newspapers.

River stages are observed daily at one hundred and ninety-one places throughout the country at 8 o'clock a. m. At some of the places observations are made only at seasons when there is apt to be high water. The records of river stages are preserved at the Weather Bureau office in Washington, D. C., and are printed from time to time. Records of stages at other than Weather Bureau stations are printed annually by the Mississippi River Commission and at irregular intervals by the Missouri River Commission.

Table I gives the river discharge, or quantity of water passing a place in cubic feet per second, at high and low water at a few places for which it is known.

In Table II is given some of the principal information in regard to Weather Bureau river stations:

(1) River station and river on which situated.
(2) Year of beginning of observations.
(3) Number of years of observations.

(4) Drainage area above place in square miles.
(5) Height of zero of gauge in feet above sea level.
(6) Height of flood line above zero of gauge in feet.
(7) Average number of days annually above flood line.
(8) Greatest number of days above flood line in a year, and the year.
(9) Highest water, and date.
(10) Average of annual highest waters.
(11) Average number of days annually above average highest water.
(12) Average date of highest water.
(13) Lowest water.
(14) Average of annual lowest waters.
(15) Average number of days annually below average lowest water.
(16) Greatest number of days below average lowest water, and the year.
(17) Average date of lowest water.

Table III contains mean stages of rivers for months, years, and for five and ten year periods at places for which there is a considerable number of years' record. These means may serve to show, in the future, by comparison with similar means, any systematic changes in river levels that may be going on, due to the extension of cultivation, clearing of forests, or change in the amount of rainfall. The mean stages of rivers constitute a far better measure of rainfall over large areas than the means of any practicable number of rain-gauge observations. The places for which mean stages are given are: Confluence, Pa., Freeport, Pa., Morgantown, W. Va., Pittsburg, Pa., Marietta, Ohio, Cincinnati, Ohio, Louisville, Ky., Evansville, Ind., Nashville, Tenn., Chattanooga, Tenn., Johnsonville, Tenn., Paducah, Ky., Cairo, Ill., St. Paul, Minn., La Crosse, Wis., Davenport, Iowa., Keokuk, Iowa, Omaha, Nebr., Plattsmouth, Nebr., St. Joseph, Mo., Kansas City, Mo., St. Louis, Mo., Memphis, Tenn., Helena, Ark., Little Rock, Ark., Vicksburg, Miss., Shreveport, La., New Orleans, La., Portland, Oregon, and Augusta, Ga.

Plates I, II, and III give the curves of river stages, or composite hydrographs at a number of places for which there are long records. Distances horizontally on the diagrams correspond to days of the year and are for intervals five days apart; the vertical distances correspond to the mean stages of the river for a number of years on corresponding days of the year.

LOCAL STORMS IN THE UNITED STATES DURING 1890, 1891, AND 1892.

With Tables of Casualties by These, and a Descriptive List of the Seventy More Severe Storms.

By Prof. H. A. Hazen.

At the beginning of 1890 a circular was prepared to be sent out to a voluntary observer or postmaster at any town where destruction was reported in the newspapers or elsewhere by local storms. This circular contained a series of questions on the time of occurrence and characteristics of these storms.

A careful watch has been kept on all storms reported by letter or by the newspapers, and a scale of 3 has been adopted to denote violence: (1) those storms showing a loss of about $3,000; (2) $20,000; (3) $100,000 and above. This scale, strictly speaking, refers to the violence of the storm and not to the property loss, but generally these are relatively the same. The scale has been widened by considering all storms that were reported which had a destruction of less than $100 as (0); then intermediate points are represented by (1−), (1+), (2−), (2+), etc.

In Table I is given a summary of all the local storms that have been reported in the newspapers and elsewhere during the three past years. These are arranged according to the scale already mentioned. Those of scale (0), 566, and scale (1—), 292, or 71 per cent of the total number, are very insignificant. We may dismiss all of these storms below a scale of (1+) as of little account, leaving a total of 70, or less than 6 per cent, of a really serious character as occurring during the three years in this country. In other words, all the local storms causing a damage of $10,000, or above, number only 70, or 6 per cent of all reported. The storms from (1) to (3+) by months are as follows: January, 14; February, 21; March, 64; April, 35; May, 35; June, 80; July, 52; August, 23; September, 1; October, 3; November, 13; December, 8; total, 349.

Table I.—Local Storms, by Months, and Violence for the Years 1890, 1891, and 1892.

Month.	Scale.										Total.
	0.	1—.	1.	1+.	2—.	2.	2+.	3—.	3.	3+.

December	12	9	7	1	.....	.....	.....	.....	.....	.....	29
Year	566	292	199	80	17	34	9	2	6	2	1,207

This gives the largest number in June. The very large number of storms in March is due to the severe and unprecedented storms of March 27, 1890, in Kentucky. It will be seen readily that very little can be gathered as to the distribution of these storms by months from records of three years.

In Table II is given a distribution of all local storms of scale 1— to 3+ by States. It seemed wise to include in this table all the storms showing any destruction, but it should be noted that of the 641 storms, 292, or nearly 46 per cent, are of scale 1— or of very slight intensity.

DEATHS BY VIOLENT WINDS.

In 1891 a form was prepared for about thirty stations of the Weather Service, calling for the names of all persons who were reported in the local papers at each station to have lost their lives through high wind or lightning. For 1890 an examination was made at Washington of several newspapers; for this reason it is probable that the reports for 1890 are not quite as satisfactory as for 1891 and 1892. Marine disasters due to high wind were not included.

In all cases where deaths are reported a circular is sent to the voluntary observer or postmaster, and in this way an accurate list of those killed has been gained a week or ten days after the local storm. There have been two very remarkable cases of a wholesale exaggeration during 1892. In Kansas, on March 31—April 1, the newspapers reported 99 persons killed and gave their names. A careful study revealed a great many *similar* names, though not exactly the same. Reports from observers gave the total as 37. Again, on May 27, in the same State, the newspapers all over the country gave a total of 69 killed, while a careful canvass made by persons on the ground made the total killed 18.

Table III shows the number of deaths by wind during each month of the three years, 1890–'92. The following is the total for each month: January, 2; February, 1; March, 190; April, 53; May, 95; June, 96; July, 90; August, 43; September, 1; October, 0; November, 0; December, 0; total, 571; per year, 190.

This summary is very interesting, and shows an uniform law of progression, except in the deaths by violent wind during March. This very large number is due to the occurrence of 141 deaths in Kentucky on March 27, 1890; 78 of these occurred in Louisville alone. A report on deaths by lightning will be found at page 510. It will be seen that deaths by wind are distributed much more uniformly through the months than those by lightning; the latter increase very rapidly from 2 in March to 216 in June and 212 in July. This shows that lightning strokes are more prevalent than violent winds during the hotter months. It will be seen that, contrary to the common

idea, deaths by lightning outnumber those by violent wind. If we omit the 141 deaths by the tornado of March 27, 1890, we shall find that only 40 per cent of the deaths from these two causes were produced by high wind. Seventy to eighty per cent of the deaths by lightning are due to persons standing under trees or unduly exposing themselves.

LIST CONTAINING A DESCRIPTION OF THE SEVENTY VIOLENT STORMS OF SCALE 2— TO 3+ DURING 1890, 1891, AND 1892.

The scale refers strictly to the violence of the storm, though the amount of loss to structures is relatively nearly the same. In many cases it has been found impossible to separate the loss to structures from that to crops. Oftentimes, also, the loss given is for a large region. Whenever possible this fact is stated. All destruction by wind has been reckoned, and in many cases these are the gales accompanying a very severe general storm, and not, strictly speaking, a local storm. This is especially the case in the winter months.

January 12, 1890.—Clinton, Ky.; 2;* great damage to buildings; 900 feet wide; 10 killed.

St. Louis, Mo.; 3; 4 p. m.; moved northeast; thunderstorm; all tall objects fell toward northeast; no whirl or funnel; débris carried northeast; 4 killed; loss, $250,000.

February 25, 1890.—Brownsville, Tenn.; 3; loss, $50,000.

March 27, 1890.—Grand Tower, Ill.; 2; 4 killed; loss, $45,000.

Metropolis, Ill.; 3; 1 killed; loss, $150,000.

Olney, Ill.; 2+; 32 houses destroyed; loss, nearly $50,000.

Bremen, Ky.; 2; 8 houses; loss, $20,000.

Kuttawa, Ky.; 2; 4 killed; loss, $15,000.

*NOTE—The figure immediately after the name of the town indicates the scale or violence.

Louisville, Ky.; 3+; occurred at 7:57 p. m.; 78 persons killed; loss, $2,250,000. This is the most severe tornado that ever visited this whole country. A full description will be found in the Monthly Weather Review for March, 1890.

April 8, 1890.—Highland Park, Ill.; 2; loss, $40,000.

May 9, 1890.—Martinsville, Mo.; 2—; time, 5:30 p.m.; roar heard; moved due east; trees thrown to southeast; 3 killed; loss, $10,000.

May 10, 1890.—Memphis, Mo.; 2—; 9:30 p. m.; heavy thunderstorm; roar heard; moved to northeast; whirl with the sun (clock-wise); trees lying to northeast; loss, $10,000.

Akron, Ohio; 2; 4:54 p. m.; light thunderstorm; roar heard; moved north 60° east; trees blown to center from both sides; loss, $10,000 to $80,000.

May 12, 1890.—Jefferson City, Mo.; 2—; about 5 p. m.; no funnel; heavy thunderstorm; no roar; no whirl; moved east; loss, $10,000.

May 22, 1890.—New London, Iowa; 2—; 6 p. m.; funnel seen and roar heard; moved ENE.; whirl counter-clockwise; loss, $11,000.

May 23, 1890.—Hopkinsville, Ky.; 2; 7 p. m.; funnel; light hail; light thunderstorm; moved northeast; no whirl; trees carried and tipped in direction of storm; 6 killed; loss, $30,000 to $40,000.

June 3, 1890.—Bradshaw, Nebr.; 3; 8:30 p. m.; funnel; hail 1 to 2 inches diameter; roar; moved to northeast; whirl clockwise; 7 killed; loss, $110,000.

June 10, 1890.—Wapello, Ill.; 2; 11:30 a. m.; funnel; hail, in size from marbles to hen's eggs; thunderstorm; moved southeast; trees thrown toward center line of storm; loss, $15,000.

June 14, 1890.—Dayton, Ky.; 2—; funnel; no hail; heavy thunderstorm; moved east; no whirl; loss, $18,000.

June 16, 1890.—Lincoln, Nebr.; 2; 4 to 5 a. m.; funnel; small hail; roar; heavy thunderstorm; moved northwest (?); buildings scattered to northeast; loss, $25,000.

June 20, 1890.—Sublette, Ill.; 2—; 4 p. m.; funnel; heavy thunderstorm; roar; moved northeast; trees fell toward center of track; loss, $10,000 to $15,000.

West Brooklyn, Ill.; 3½ miles south; 3; funnel; heavy thunderstorm; roar; whirl counter-clockwise; trees fell toward center; 12 killed; loss, $100,000 to $200,000.

June 22, 1890.—Sweetwater, Nebr.; 2; 3:20 p. m.; funnel; thunder heard; roar; moved southeast and northeast; loss, $25,000 to $50,000.

July 7, 1890.—Fargo, S. Dak.; 3; about 2:30 a. m.; no funnel; roar; moved to southeast; trees fell to southeast; 7 killed; loss, $75,000 in Fargo; $25,000 in Moorhead, Minn.

July 8, 1890.—Cleveland, Ohio; 2+; 6:10 to 6:40 p. m.; no funnel; light thunderstorm; no roar; moved southeast; loss, $100,000, estimated.

July 13, 1890.—Lake City, Minn.; 2—; loss, $10,000, estimated.

Lake Gervais, Minn.; 2—; 5 p. m.; funnel; heavy thunderstorm; roar; moved southeast; whirl counter-clockwise; trees on north side thrown northeast; on south side, southeast; 6 killed; loss, $10,000.

July 17, 1890.—Allentown, Pa.; 2; about 4 p. m.; no funnel; moved southeast; no whirl; trees fell to south; 1 killed; loss, $20,000 to $30,000.

Ashland, Pa.; 2; 5:40 p. m.; no funnel; heavy thunder storm; roar; moved to southeast; trees blown over to southeast; loss, $30,000 to $50,000.

Hellertown, Pa.; 2; 4:30 p. m.; heavy thunderstorm; roar; moved southeast; trees blown over to southeast; 1 killed; loss, $30,000.

July 26, 1890.—South Lawrence, Mass.; 2+; 9:13 a. m.; funnel; no hail or thunderstorm; roar; moved north 60° east; most trees blown toward or in direction of path; 8 killed; loss, $50,000; a full account in Monthly Weather Review of July, 1890.

August 19, 1890.—Harveyville, Pa.; 2; 5 p. m.; funnel; no hail; heavy thunderstorm; moved east northeast; whirl to left; 3 killed; loss, $25,000.

Wilkes Barre, Pa.; 3+; 16 killed; loss, $400,000; full account in Monthly Weather Review of August, 1890.

August 21, 1890.—Beaver Creek, Md.; 2—; funnel; thunderstorm; loud roar; moved north-northeast; whirl to right, clockwise; loss, $13,000.

October 16, 1890.—Maxton, N. C.; 2—; 3:30 p. m.; funnel; heavy thunderstorm; roar; moved northeast; whirl clockwise; loss, $15,000.

April 15, 1891.—Hansford, Tex.; 2; 7 p. m.; funnel; heavy hail and thunderstorm; roar; moved northeast; trees toward northeast; balls of fire seen; 2 killed; loss, 25,000.

May 20, 1891.—Centralia, Mo.; 2; 3 to 3:30 p. m.; funnel; heavy thunderstorm; roar; moved northeast; whirl to right, clockwise; trees to east; 1 killed; loss, $25,000 to $50,000 in county.

Mexico, Mo.; 2; about 3:20 p. m.; funnel; heavy thunderstorm; loud roar; moved due east; whirl to left, counter clockwise; 3 killed; loss, $25,000.

August 13, 1891.—Ellsworth, Minn.; 2—; loss, $15,000.

November 23, 1891.—Washington, D. C.; 2+; wind rush; 1 killed; loss to structures, $100,000; full account in Am. Met. Jour., Feb., 1892, p. 460.

Frostburg, Md.; 2; roar; moved a little north of east; loss, $35,425.

Hanover, Pa.; 2; no hail; thunderstorm; roar; moved to southwest· trees blown with storm; 1 killed; loss, $20,000.

Pittsburg, Pa.; 2+; 10 to 11 a.m.; no funnel; light thunderstorm; no roar; moved northeast; no whirl; 1 killed; loss, $40,000, probably, in vicinity.

March 31, 1892.—Horton, Kans.; 2—; 1 killed; loss, $50,000.

Kiowa, Kans.; 2—; moved northeast; trees fallen mostly north and east; loss, $15,000

Saline, Kans.; 2; funnel; no thunderstorm; roar; moved north-northeast; whirl counter-clockwise; trees thrown out from track; two clouds met; loss $100,000 in vicinity.

Towanda, Kans.; 2; funnel; heavy thunderstorm; moved north; whirl counter-clockwise; trees fallen along and in track; 8 killed; loss, $15,000.

Nelson, Mo.; 2+; 6 p.m; funnel; light thunderstorm; roar; moved northeast; whirl counter-clockwise; loss, $90,000 in vicinity.

April 1, 1892.—St. Joseph, Mo.; 2—; 2 a.m; loss $20,000.

April 3, 1892.—Scottdale, Pa.; 2—; no funnel; heavy thunderstorm; roar; moved northeast; trees blown over in direction of storm; loss, $10,000.

Gainesville, Tex.; 2—; funnel; heavy thunderstorm; roar; moved northeast; loss, $8,000.

Pine Bluff, Ark.; 2; 11:55 a.m.; no hail; no thunderstorm; roar; moved northeast; trees blown over in direction of storm; loss, $15,000 to $20,000.

May 27, 1892.—Harper, Kans.; 3; 7:40 p.m.; funnel; no thunderstorm; terrible roar; moved east-southeast; no whirl; trees with storm; 4 killed; loss, $400,000.

Wellington, Kans.; 2; 9 p.m.; heavy thunderstorm; roar; moved east-northeast; trees blown over to east; 12 killed; loss, $50,000.

May 31, 1892.—Durango, Tex.; 2—; 6:30 p.m.; funnel; moved northeast; whirl to right, clockwise; 6 killed; loss $12,000.

June 5, 1892.—Cleburne, Tex.; 2; 8 p.m.; sharp thunderstorm; roar; moved southeast; whirl clockwise; trees blown over south and north; loss, $8,000.

June 13, 1892.—Galva, Ill.; 3; 7:45 p.m.; no funnel; severe thunderstorm; whirl clockwise; balls of fire seen; 1 killed; loss, $150,000 in vicinity.

June 15, 1892.—Dunbar (near), Minn.; 2—; loss, $10,000.

Easton, Minn.; 2; 4:30 p.m.; funnel; no thunderstorm; roar; moved east; whirl like left-hand screw; 4 killed in county; loss, $16,000.

Fairmont, Minn.; 2; funnel; roar; moved northeast; whirl counter-clockwise; 2 killed; loss, $20,000 in county.

Hartland (one-half mile north), Minn.; 2—; 5:30 p.m.; funnel; heavy thunderstorm; roar; 1 killed; loss, $35,000 in county.

Minnesota Lake, Minn.; 2; 5 p.m.; funnel; 12 inches rain; heavy thunderstorm; roar; moved east; 4 killed; loss, $16,000 in vicinity.

Wells (4 miles north), Minn.; 2; funnel; heavy thunderstorm; roar; moved east; loss, $20,000 in vicinity.

June 22, 1892.—Fredericksburg, Iowa; 2+; 5 p.m.; funnel; heavy thunderstorm; roar; moved southeast; 1 killed; loss, $50,000 in two counties.

Sumner, Iowa; 2+; 6 p.m; funnel; roar; moved east-southeast; whirl counter-clockwise; 1 killed; loss, $40,000.

July 1, 1892.—Mason, Nebr.; 2; no funnel; thunderstorm; roar; moved east-northeast; trees fallen in direction of storm; storm rolled along as a log; loss, $25,000 to $40,000.

July 2, 1892.—Carey, Ohio; 2—; 11:50 p.m; no hail; light thunderstorm; roar; moved southwest; loss, $15,000.

July 13, 1892.—Springfield, Ohio; 2; 11 a.m.; heavy thunderstorm; funnel; loss, $20,000.

July 15, 1892.—Saratoga Springs, N. Y.; 2; loss, $10,000.

July 24, 1892.—Barberton, Ohio; 2; 2 killed; loss, $25,000.

July 25, 1892.—Algona, Iowa; 2; no funnel; no roar; heavy thunderstorm; loss, $50,000 in county.

This list of the 70 more severe winds is given here to show the character of the storms reported. Out of the 1,207 cases reported by the newspapers, 1,137, or nearly 95 per cent, are scarcely noticeable for severity. It should be noted that no attempt can be made to determine the relative violence or frequency of these storms in the different States; it will require a careful compilation of all storms for fifteen or twenty years before this can be done.

CASUALTIES DUE TO LIGHTNING.

By A. McAdie.

Foreign countries, particularly Germany and France, nave recognized the importance of obtaining statistics concerning the loss of life through hail storms, lightning, high winds, etc. For Prussia, statistics are available even to the number of houses struck by lightning, the number of fires started, the character of the roofing, of the soil, of the protection, etc. In 1891 the Weather Bureau issued to its observers instructions to report from month to month the names (with corroborative dates and places) of all persons killed by violent windstorms, tornadoes, and lightning. During 1890 somewhat similar statistics had been collected, but the system put in operation in the following year was more thorough and complete. Mr. H. F. Kretzer, of St. Louis, Mo., has for years tabulated the number of deaths due to lightning, and has kindly placed some of his material at the disposal of the Weather Bureau. His sources of information were 192 newspapers—daily, weekly, and monthly. In preparing the Weather Bureau lists, observers were directed to examine all daily papers published in their respective cities, all local sources of information, and in brief to make full lists. To verify the names and dates thus obtained, circular letters were sent to postmasters and voluntary observers. In this way, and by close scrutiny, a great number of duplicates were weeded out, and exaggerated reports reduced to proper limits.

To get at something like a commercial estimate of the damage done to property by lightning, I have made use of the "Chronicle Fire Tables" for the six years, 1885–'90, and find that lightning, considered as an *indirect* cause of fire, led to 2,223 fires, or 1.3 per cent of the whole number of fires, and the loss $3,386,826, or 1.25 per cent of the whole amount lost through fire. From the standpoint of insurance, fires by lightning are considered to be of *regular* occurrence. I have also made a table based upon the information given in the "Chronicle Fire Tables," showing in detail the losses during 1890. The total number of fires, 625; the total loss, over a million and a half. For the period of seven years, the total is 1,550 barns, stables, granaries; 64 churches, 409 dwellings; 7 electric-light stations: 10 grain elevators; 35 oil tanks; 39 railroad depots; 14 telegraph and telephone offices; 9 schoolhouses, etc.

Deaths Caused by Lightning during Three Years, according to the Weather Bureau Records.

	1890.	1891.	1892.		1890.	1891.	1892.

A BALLOON ASCENSION.

By Prof. H. A. HAZEN.

On October 27, 1892, during one of the driest times ever known at Washington City, it was decided by the Government experimenters on rain-making to make an ascension to determine the conditions of the atmosphere. The balloon used had a capacity of about 9,000 cubic feet, and when inflated with hydrogen was able to lift two observers and 60 pounds of ballast. It is doubtful if such a small balloon has ever made so high a voyage with such a load. The gas, after passing through iced water, was conveyed by a cloth tube some 40 feet long to the balloon, so that its temperature was that of the air. The start was at 15:33, and the ascent was 500 feet per minute for six minutes. In fourteen minutes we were at nearly 5,000 feet, and here the balloon, having lost some gas at the neck, poised for about six minutes and then fell rapidly nearly 1,000 feet, when a liberal use of ballast caused its ascension to the highest point attained, 9,400 feet at 16:26. At this high level we remained about four minutes and then returned quite rapidly. We landed at 16:59, 2 miles east of Suitland, Md., on the farm of E. D. Rude, having gone 9.4 miles in a nearly due-east direction.

The accompanying table contains the observations made as rapidly as possible. The computations are made from the observations as recorded, though it is evident that a little allowance must be made for the lagging of the aneroid, and for the interval between swinging the thermometers, reading them, the aneroid, and the watch. At the highest point I have added 50 feet for the aneroid. The apparent slight effect of the Potomac on the moisture of the air is to be noted. If anything, there was less cloudiness over it than on either side. The saturated stratum, at 8,500 feet, is interesting, as it was less than 500 feet thick, the relative humidity, at 9,400 feet, being 30 per cent less.

The great necessity now is to make more frequent ascensions, especially at the time of rain. We ought to learn the behavior of this saturated stratum as rain comes on. How it thickens and descends, etc. The whole voyage demonstrated the beautiful and safe character of such exploration.

Mr. Ellis, the aëronaut, also made humidity observations. The sling psychrometer proved itself a most excellent apparatus, responding promptly to all demands upon it and giving a very accurate record of the exact moisture conditions of the air.

OBSERVATIONS DURING A BALLOON ASCENSION, OCTOBER 27, 1892.

REPORT ON THE RELATIONS OF SOLAR MAGNETISM TO TERRESTRIAL MAGNETISM AND METEOROLOGY.

By FRANK H. BIGELOW, *Professor of Meteorology.*

METEOROLOGY AND TERRESTRIAL MAGNETISM.

In October, 1891, having received an appointment as professor of meteorology in the U. S. Weather Bureau, I was assigned to a study of the relations of the physical forces that are observed in meteorological and magnetical phenomena, respectively. This problem is a logical continuation of some researches that had been carried on in a private capacity, from which there arose a probability that some connection between these two branches of science does exist, although hitherto having eluded the efforts of scientists to discover what it is.

The nature and importance of the question involved in this investigation should be clearly understood. It has two aspects from which it may be viewed. On one side it is perceived from an inspection of the literature of these two subjects, in which is recorded the observations of meteorologists and magneticians in their special departments, as well as the efforts to elucidate their meaning by ascribing them to simple and fundamental laws, that there has been accumulating a vast amount of data, which is at present in a congested state, not being understood. The large volumes of observations, often extending over a series of years, constitute a set of records of great value intrinsically, and yet they are becoming oppressive by their very dimensions, for lack of a clear idea for their proper classification and significance. Throughout the accumulation of these painstaking observations there has run a vein of suspicion in many minds, amounting almost to certainty in some, that these two subjects, though apparently distinct in certain respects, yet in reality constitute one and the same body of phenomena, emanating from a single fundamental cause. This impression is very much strengthened by the inability of either meteorologists or magneticians to build a structure of cause and effect for their own departments that satisfies the best critics. So far as meteorology is concerned, its task being to give an account of the distribution of the atmosphere over the surface of the earth, the winds, storms, and other natural processes arising from its disturbed equilibrium, no one supposes that the problem is completely solved.

The best efforts have been made along the lines of thermodynamics as the moving cause and dynamical mechanics as the procession of effects, much talent, if not genius, having been expended on these mathematical and physical relations. Yet confessedly the mathematical solutions are restricted to such simple ideal cases, because of the analytical complexity of the equations, that they are inapplicable to nature; and in the physics of the subject there are immense gaps over which no bridges exist. The outcome of this state of things is that meteorology remains a purely empirical subject, its immense usefulness to mankind making even this imperfect development of extraordinary value. With regard to magnetism the case is even worse than with meteorology; for it may be said without exaggeration that neither in analytical treatment since the days of Gauss nor in theoretical physics since the researches of Faraday has any progress been made, and, except in some details of instrumental registration for continuous observations, the subject remains where it was forty years ago. Observations have accumulated in large and valuable proportions, but on

the whole the outlook has been discouraging, because there has been no clew to the law of causality underlying the complex and flickering variations of the magnetic forces.

If it were possible to discover the fundamental relations which go to the bottom of these subjects, and especially if the key to the connection between them could be found, the result would be so largely beneficial to the advancement of these branches of physics that considerable risk might justly be incurred in entering upon a line of investigation that offered a fair hope of moderate success. It was such a process of thought as the one just traversed that induced me to make the attempt whose progress forms the subject of this report. Nor was it an embarkation upon an untried voyage, without a rational ground for belief that there would be a reward at the end of it. The development of the past ten years in the physics of electricity and magnetism had gone so far as to show that Maxwell's view of the electro-magnetic nature of the radiations of the sun, received at the earth as heat and light, must be accepted as the basis of future research in this department of science. From certain studies on the nature of the solar corona, which though inconclusive on account of the imperfect data secured from the eclipses of the sun, yet pointed strongly to the magnetic polarization of the sun, I had conceived the belief that a direct application of these premises to the whole set of phenomena forming the physical connection between the sun and the earth, and exhibited chiefly in magnetical and meteorological conditions at the earth, ought to be seriously undertaken.

My idea was that the sun, being magnetic and electro-magnetic itself, should by the rotation on its axis present these forces to the earth in such variable strengths as ultimately to produce some of the fluctuations that are observed at this distance from it. The perplexity consisted at the outset in an entire ignorance of the exact end of the thread that was to be the clew through the labyrinth of observed facts, in the difficulty of reducing the mathematical considerations to so simple a process as not to overwhelm the trial with intricate computations, and finally in the almost unanimous consensus of opinion that such forces if they did emanate from the sun, would be too feeble to produce any periodic influence at the distance of the earth. Fortunately I had no difficulty in overlooking the last fact. As regards the second it seemed that a process of reduction which was already in operation to a limited extent offered the required simple analytical conditions; and with regard to the clew, confidence was felt that it would soon be detected with some certainty, if it existed, before an unreasonable amount of labor had been expended.

It will be necessary to pass almost without intermediary developments from this statement of the problem to the results of the investigation, so far as they have been secured, because the proof of the results will require a fuller exposition than is here possible, such as is to be prepared shortly, and since a brief summary of the most important conclusions may be acceptable, disentangled from the technical methods employed in obtaining them from the observations. The results naturally divide themselves into four parts, which are distinct and yet dependent upon each other. These are as follows:

I. The sun, a magnetic and electro-magnetic body.
II. The coronal field and its characteristics.
III. The radiant field and its characteristics.
IV. Their relations to meteorology and long range predictions of the weather.

THE PHYSICAL CONSTITUTION OF THE SUN.

The result of my study on the solar corona, depending upon measurements of the lines given in the photographs of the eclipses of July 29, 1878, January 1, and December 22, 1889, goes to show that the sun has two poles of magnetization, one in each hemisphere, situated about $4\frac{1}{2}$ degrees from the axis of rotation, and separated from each other 102 degrees in longitude, the south coronal pole preceding. The visible streamers of the corona, which appear grouped about these poles in peculiar curves, do not spring up from the sun indifferently all over its surface, but their bases are confined to two narrow belts about 15 degrees wide, one in each hemisphere, whose central line is between 33 and 34 degrees from the coronal poles. These facts suggest many conclusions regarding the nature of the sun, but this paper will be limited to a recital of the facts produced by the investigation.

It next became a matter of importance to determine the period of the solar rotation, because if this indication of polarization of the body of the sun be true there must be a nucleus in which such permanent magnetization resides, and thence there should be definite time of rotation. The first attempt to discover this was from a discussion of the intervals between the three eclipses, an effort being made to adjust the positions of the coronal poles to a single period. Guided by the observations of the sun-spot motions and the current theories of the extension of their periods toward the solar poles, I supposed that there must have been twelve rotations between the eclipses of January 1 and December 22, 1889, and proceeding on this assumption concluded that the synodic period near the poles was 29.64 days. This turns out to be wrong because there should have been taken thirteen and a fraction revolutions between these two eclipses instead of twelve revolutions; my final period being 26.68 days.

It is impossible to reproduce fully the process of obtaining this period, because the work is extensive; but it is so important, being the key to my development of the subject, that I will briefly indicate the method. If the sun is a magnetic sphere, in which the magnetism is distributed with irregular intensity throughout the mass, in the same way that the permanent magnetism of the earth deviates from the simple law of the uniform spherical magnet, then in the field outside the sun, as far as its strength reaches into space, the lines of force being propagated through the ether, these variations of intensity will be found by an observer passing along it from point to point. If this field reaches to the earth the rotation of the sun on its axis sweeps the field past the earth, presenting all phases of it in the synodic period of rotation, so that if it is of finite or measureable dimensions it can be studied just as well as if the observer were on the sun. All that is needed is a delicate mechanism for such measures. This has been fortunately provided, partly by nature and partly by man's invention. For surrounding the earth itself is a system of magnetic lines of force which begin at the earth's south pole, sweep wide through space and return to the north magnetic pole, the subsidiary lines holding appropriate positions. These lines of force may be compared to a delicate system of springs, sensitive to every touch from similarly constructed magnetic springs. Now the magnetic springs from the sun do touch these terrestrial springs, bend them slightly but surely, so that their direction and force at any point on the surface of the earth is constantly changing in response to the solar pressure. What the modified or variable force and direction of the earth's field is at any time, can be measured with almost incredible accuracy in magnetic observatories, and in fact it is these very fluctuations that are recorded on their continuous photographic traces. When carefully classified these variations separate themselves into two distinct types, one due to the rotation of the earth on its axis, with the modification produced annually by the orbital motion about the sun, and the other due to the rotation of the sun on its axis in about twenty-seven days, carrying its magnetic field through the earth's field. The former, that is, the diurnal period, is in response to another magnetic field emanating from the sun, not yet described, which I call the *radiant* field, and which comes parallel to the ecliptic, while the twenty-seven-day period is due to the *coronal* field, which approaches the earth perpendicularly to the plane of the ecliptic.

My investigation has been to disentangle the operation of these two solar fields, which though acting simultaneously yet have such different actions as to render this process possible. In order to complete my statement regarding the nature of the sun, before passing on to describe these two fields it seems necessary to suppose that the radiant field, which is propagated in linear directions like rays of light and heat, all of which are forms of the radiant energy of the sun, originates in the electrical discharges from the atoms of ponderable matter composing the photosphere, whereby they act as condensers, and communicate rapidly alternating oscillations to the ether, which propagates the disturbance across the intervening space, according to Maxwell's theory. If we can dintinctly detect this field at the earth, it becomes an important line of evidence in confirmation of this view of the subject. Regarding the sun itself, it is our belief that the photosphere is a great electromagnetic shell of ponderable matter held off from the rigid nucleus, at some fixed distance due to solar physical conditions, as clouds condense at a certain average height above the surface of the earth. In this shell the radiant field has its seat, in the nucleus the coronal field has its base, each being controlled by separate sets of laws, which are yet related to one another. Furthermore, I find that the period of rotation of this coronal field, namely,

26.68 days, is precisely that of the sun spots at the sun's equator, which also argues that the sun rotates as a solid. The so-called acceleration of the sun's equatorial belts is therefore a fiction of astronomy, the truth being that the sun-spot belts up to 35° of latitude show a retardation or anti-rotational motion, and remind us of westward-blowing constant trade winds in similar localities on the earth. Having thus exposed our conception of the problem, our results confirming it in the coronal field, the radiant field, and in meteorological phenomena will be briefly reviewed.

THE CORONAL FIELD.

The variations, derived from the magnetic forces, as observed at Los Angeles, Toronto, Greenwich, Paris, Pola, Prague, Vienna, Pawlowsk, Tiflis, Zi-ka-wei, and Batavia for the year 1887, and for the European stations for years extending from 1878 to 1891, have been reduced to rectangular coördinates, dx, dy, dz, and then transformed to polar coördinates, σ, ς, α, β. These latter quantities signify, σ the horizontal component on the plane of the horizon at the station, ς the resultant force in space that produced the variation of the normal field, α the angle that this force makes with the plane of the horizon, and β the angle in azimuth that the component σ makes with the magnetic meridian, counted in the direction, N., W., S., E.

When the azimuth angles β are inspected, after tabulation for all the stations, it is seen that they are governed by a distinct law. Laying aside the irregularities arising from local conditions and instrumental errors, it is clear that these forces act generally northward or southward; that they move simultaneously in one of these directions or the other all over the hemisphere, showing that they are necessarily of cosmical origin; and they have certain dates of sudden reversals, when they all turn from north to south, or oppositely; also these dates of reversals occur periodically. The final period for the principal reversal is 26.68 days, with the epoch June 12.22, 1887; and this is the time when the sun's south coronal pole is directly in the plane between the center of the sun and the earth, the plane standing perpendicular to the ecliptic. This is the synodic rotation of the sun, and from it an ephemeris has been constructed covering the last quarter of the century, our epoch falling near the middle. The ephemeris gives the dates of the recurrence of the south pole of the sun in the situation described.

Further consideration of the secondary dates of reversal shows that this period is subdivided into unequal intervals. Following the beginning of each period, there is another reversal in eight days, so that the twenty-seven-day period is subdivided into eight and nineteen days, respectively, this peculiar sequence of reversals showing that the north coronal pole of the sun follows the south pole in eight days, or at an interval of 102°, and that then the south pole comes again in nineteen days. There are many variations which depend upon a set of forces bound up with the eleven-year period whose investigation is not yet completed, by reason of the extensive computations required in preparation for it. This period and epoch have been applied to the placing of the model of the sun's corona, prepared from investigations of the eclipses, with the result that the agreement of the projections of the model with the pictures of the corona, when reduced to the same scale and rigorously superposed, is satisfactory to a marked degree. From the coronal photographs this interval between the poles, and from the reversals of the terrestrial magnetic field, is found to be 102°, thus forming a basis for confidence in the foundation of the investigation.

The study of the altitude angle α shows that when the coronal field is acting south the value of α is +41°, and that when it is acting north the value of α is −41°, which in accordance with the adopted notation means that this field enters the northern hemisphere nearly parallel to the earth's axis of rotation, having been diverted from the direction perpendicular to the plane of the ecliptic by the rotation of the earth on its axis, the other component having been screened off or used up in connection with the earth's permanent magnetism, which may be the true origin of the force that gives it a slow secular variation.

The study of the forces σ and ς, when collected on our period, gives two curves similar to each other in all respects throughout their extent, thus proving that the angle α is constant, or that these forces come from a field having a fixed direction. The first two curves of the accompanying diagram [Plate IV] give the component σ and the resultant ς. The mean curve, dotted line, is a single periodic curve, with minimum on the ninth day and maximum on the twentieth day, with a small secondary variation on the twenty-fifth to the twenty-seventh days. Superposed upon this is

another curve, with four maxima, on the first, ninth, fifteenth, and twenty-first days, four minima, on the seventh, twelfth, eighteenth, and twenty-fourth days, with two small secondary inflexions on the fifth, sixth, and twenty-fifth to the twenty-sixth days. If the intensity of the magnetic field along the equator of greatest intensity of the earth be reduced to a curve of equal extent and amplitude, it is seen to agree closely with this mean curve in shape and inflexions. This terrestrial curve is related to the North American, the Siberian, the Australian, and possibly the South Pacific poles of intensity, and they can be located in longitude relatively to the curve just described. Now, if the magnetic curve ς be wrapped about a central pole A, corresponding to the base line of abscissas, it is found that the mean curve has a peculiar situation. It can be represented by an arc of a circle struck from a center B, while only two short arcs, from the fifteenth to the seventeenth days and the twenty-fifth to the second days, lie outside of it, and these can be covered by an arc from a center C and a center D, respectively. The position of the centers A, B, C, D, are as follows:

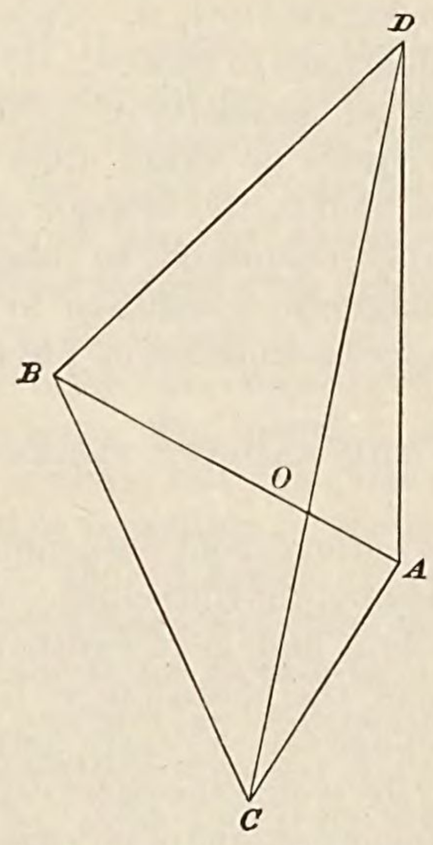

FIG. 23.—Diagram of centers of magnetic curves.

As stated these centers or poles were each found by trial from the curve that depends absolutely upon observations at the earth. Let it be noted that the angle $B\ A\ C = 90°$ and the angle $B\ O\ C = 102°$, precisely, the latter again agreeing with the coronal result, and the outcome of the β-reversals. If now A, B, C, D are taken as magnetic poles, it is found that the diagonals and sides of the quadrilateral are strictly related to the crests and hollows of the curves σ and ς, $A\ C$ extended meeting the maxima of the second and sixteenth days, and $A\ B$ the maxima of the ninth and twenty-first days, while the other lines all strike into the peculiar curvatures of the superposed or enwrapped curve. This seems to indicate that the sun has four poles of intensity arranged in the order of magnitude—A the strongest, B the next, C the next, and D the weakest, just as the earth has, and that C corresponds to the south pole, B to the north pole of the corona, my epoch being the time when the pole C is opposite the earth. When the field reverses between C and B, the impulse comes to the earth generally from north to the south, and by our conception of the normal field it repels an isolated positive magnetic pole southward, and hence the north coronal pole of the sun is probably positive, the south pole being negative, a conclusion also reached in other ways. Hence by similarities, the south coronal pole C is negative, and corresponds to the North American pole; the north coronal pole B is positive and corresponds to the Australian pole; the pole D is negative and is like the Siberian pole. Furthermore, if the lines of the quadrilateral are extended into space, and if through each pole sets of three perpendiculars are dropped upon the opposite sides and diagonal, respectively, and likewise extended to meet the first lines, and if the points of intersection be connected by a curve passing through them which may be regarded as a locus of intensity, the curve thus formed is similar to the curves σ and ς in all their variations, but smaller, so that at least they may be said to belong to the same family. This also becomes a

powerful argument in favor of our fundamental conception regarding the magnetic constitution of the sun.

Next the record of sun-spot areas as given in the Greenwich volumes were arranged on this period for 1886, 1887, the means of the twenty-seven periods taken and the variations from the general mean, plotted as a curve, after reducing to the same amplitude. This curve agrees throughout with the mean curve of the resultant s, as displayed in the diagram. It shows that the maximum of sun spots occurs along the axis A B and opposite the negative pole A, the minimum occurring opposite the pole B, but chiefly it shows that the sun spots are distributed on the surface of the sun in localities, in conformity with and in dependence upon the magnetic system of the sun.

I will briefly sum up a long investigation on the magnetic storms or disturbances at the earth, by saying that they all come in along the coronal field perpendicular to the ecliptic and are therefore dependent upon sudden fluctuations in the magnetic system of the solar nucleus. It results from the values of the resultant s that its mean at the earth is 0.000115 C. G. S., and that in severe magnetic storms it rises to 0.002500 C. G. S. This implies a normal intensity of magnetization of the sun of 269 C. G. S., which rises to 5850. C. G. S. in the case of great storms. Steel when magnetized to its maximum has an intensity of 1390 C. G. S., so that by comparison with steel the sun's forces of magnetism require no strain upon our judgment, as to their credibility. From these data the conditions of the field in the interior of the sun, and exterior to it throughout the planetary system, can be readily computed, so that the traces of our magnetic observatories give us the pulse beat of the magnetic circulation in every part of the the solar system, a fact of profound interest and importance to students of physical science.

THE RADIANT FIELD.

As already described, besides the coronal field perpendicular to the plane of the ecliptic near the earth, there is another field, in the plane of the ecliptic, called the radiant field, agreeing with the direction of the ether energy of light and heat emitted from the sun. It originates in the electric discharges between the atoms of the photosphere, is electro-magnetic, is propagated with the velocity of light, and in the atmosphere of the earth and in the earth itself undergoes a complex series of transformations of energy, by which the short rapid waves are lengthened or destroyed, the work thus used up appearing in transformations of physical phenomena. The proof for the existence of this field consists in tracing out the effect produced upon the normal terrestrial magnetic field, in the diurnal periodic variations. A similar treatment of the residulas, which arise by comparing the monthly mean with the hourly values, gives the vectors or the disturbing forces due to the radiant field. For this purpose such magnetic stations, thirty in number, distributed widely over the earth, from Kingua Fjord to Hobarton, as have hourly observations extending throughout at least one year, have been completely reduced and the results put into intelligible shape. The final deflecting forces have been collected month by month, summed by six months, those in which the sun is north of the equator forming one group, and those in which the sun is south forming the other group, and finally the mean for the year taken for σ, s, α, β. Then these annual forces, which represent the mean condition of the field when the sun is on the equator, each individual result being the mean of 365 separate observations, is transferred to a 30-inch globe by means of wires set in at the proper angles α, , and of such length that 1 m m. represents 0.00001 C. G. S. As the earth revolves the stations are carried through the field and at each local hour, relatively to the field, the position of the deflecting force is recorded.

The finally constructed field surrounding the earth is exceedingly complex, and a description of it here is quite impossible, though some of the leading features of it may be mentioned. The fundamental law of the entry and departure of the forces from the earth conforms to the tangent law of magnetic refraction, the index being about 1.25. In the northern hemisphere the field points towards the sun, in the southern away from the sun, so that the earth is in a magnetic couple, the radiant field showing a potential fall from the sun outwards. The plane of symmetry of the field is not on the meridian of the sun, but it is thrown westward, by the rotation of the earth, through an angle of about 23° in the northern and 15° in the southern hemisphere. The field shows a series of five parts, gradually changing within their areas, but discontinuous as

to each other. These are the polar field, the north-mid-latitude field, the equatorial field, the south-mid-latitude field, and the south-polar field. The polar field is three or four times as strong as the others, in which the forces concentrate in two polar points and act along the meridians; the northern field points across the meridians, the discontinuity being along the belt of the auroral maximum of frequency; the equatorial field points north or south, and the southern field across the meridians, away from the sun. The strength of the radiant field is about 0.000135 C. G. S., being a little greater than the coronal field. A complete discussion of the numerous physical problems arising from these facts can not now be attempted, but great light is thrown upon many of the observed physical phenomena that have been perplexing to scientific research. It seems especially to confirm in a marked degree the theory of Maxwell regarding the electro-magnetic constitution of the radiant ether waves.

THE APPLICATION OF THESE TWO FIELDS TO THE PROBLEMS OF METEOROLOGY.

I can not here undertake to elaborate the whole of the bearing of these two great physical fields of force upon the phenomena of the atmosphere, as it opens up a vast region of study. Only the facts will now be stated. On applying the coronal period with its dates to the variations of atmospheric pressure, the temperature, the relative humidity, the atmospheric electric potential fall, and the recurrency of stormy or quiet weather conditions, for the years 1886, 1887, at the same stations for which the magnetic observations were discussed, there results a set of curves of similar form, as shown in the diagram, to those derived from the variations of the magnetic field and the mean sun-spot curve. There are the same number of maxima and minima, and they occur on the same days of the period throughout. The drawing appended to this report is intended merely to show that the maxima, the minima, and the nodes of the several curves fall on about the same days of the period. A complete exposition of the data is impossible in this connection, and therefore no values are assigned to the ordinates of the several curves. The conclusion is unavoidable that all these meteorological elements of the weather are direct functions of the solar magnetic field, and being dependent upon it for variations of intensity and for reversals in the impressed forces, they are subject to a periodic law of prediction. This has been verified in numberless ways, extending back and forth for fifteen years, so that this statement is made with confidence. Since these impressed forces are large relatively to the inertia of the atmosphere, it will be seen that the thermodynamic mechanics, though still playing an important part in the general distribution of the atmosphere, is yet supplemented by the impressed energy of the polar radiant field of force. It is evident that these conclusions have not been reached heretofore owing to the pernicious use of the calendar months for periods, by which the variations of the true period are totally obscured when summed together in a periodic recurrence. Hence the primary reform consists in adjusting the computations of meteorology to the coronal period.

I have not been able to carrry the investigations much beyond this point at the time of writing this report, but there seems to be very strong evidence for seeing in the semi-diurnal range of the barometer a close correspondence, if not dependence, upon the distribution of the radiant field. If this proves to be the case, then we shall look for the same function in the temperature, relative humidity, and atmospheric electricity, with a corresponding contribution to weather phenomena. Since the coronal magnetic field yields its part to weather changes, it is not unnatural to look for the same in the radiant field. Still the two fields have different fundamental properties, the former being a rotating or vortical field and the latter an alternating field, so that the resulting phenomena may be unlike. It seems to me that the grand problem of the meteorologist is that of atmospheric absorption, a complete account of the transformation of the ether-waves from the frequency and amplitude they have on entering the atmosphere to their final decay, disintegration, and distribution in other forms of energy. The only path for such a programme is through the study of electricity and magnetism, in correlation with the other forces, especially atomic and molecular, that are the peculiar province of the experimental physicist.

U. S. WEATHER BUREAU,
Washington, D. C., March 10, 1893.

REPORT ON CONDENSATION OF ATMOSPHERIC MOISTURE.

By CARL BARUS, *Professor of Meteorology.*

My appointment in the United States Weather Bureau began with the 7th of September, 1892. At the outset considerable work had to be done, with the object of getting the physical laboratory, which passed into our hands through the courtesy of the director of the Geological Survey, Maj. J. W. Powell, and of Mr. Clarence King, in readiness for meteorological work. Fortunately this could be done at the expense of a minimum of time and labor, for the old quarters of the laboratory in the National Museum were not immediately to be vacated. Our thanks are, therefore, due to the secretary of the Smithsonian Institution, Prof. S. P. Langley, and to Mr. G. Browne Goode, of the National Museum, as well as to Maj. Powell and Mr. King, for the material assistance which they have so kindly tendered us, for it was thus possible to launch the new work of the Bureau unobtrusively and almost without expense.

(1) In defining my duties I may say that the physical problems connected with the condensation of water from moist air was first considered. The agencies which lead to the formation of rain can not be said to be accurately and fully known, and to some extent the raindrop is as yet a physical mystery—remembering always that vague or loosely general inferences are of no professional value. The chief of the Weather Bureau has been pleased to leave me at liberty as regards methods of work and modes of attack, and I have therefore endeavored to look at phenomena involving a change of the physical state of aggregation from the broad points of view suggested by the epoch-making work of Van't Hoff, Arrhenius, Ostwald, and others. I have considered condensation in general, taking into account both the change of physical state from solid to liquid, as well as the more specific case from liquid to gas; and this no matter whether the active agent is heat (fusion, boiling, evaporation) or solution (liquid or gaseous). It is in keeping with the modern theories of solution just specified to group all these phenomena under a common head, a method which has already been applied with success by Blümcke.

With the physics of the solidification of a liquid by pressure at any given temperature, or by temperature at any given pressure, my earlier work on the Geological Survey had already made me familiar; and as the apparatus previously used was still available, I commenced my new work by investigating the conditions under which a solid is precipitated from solution. This research is finished, at least as far as I can now venture to enter into it. The chief feature of the results is the occurrence of a pronounced volume lag, in virtue of which solution at a given temperature takes place at a lower pressure than the corresponding precipitation. Similarly solution at a given pressure takes place at a higher temperature than the precipitation, though these effects are not always so easily observed. Moreover, when precipitation does occur from solution, it is partial. In this respect the present behavior differs in a measure from the corresponding case of freezing from fusion. In other words, the solution phenomenon contains a clear-cut case of chemical equilibrium, and its close relation to the meteorological problem is therefore already manifest. For in both

cases the tendency to supersaturation and the partial precipitation of the dissolved substance (water vapor in air in the latter case) are marked features.

(2) Returning from this digression to the subject chiefly at issue, it is clear that the method applicable to the study of the condensation from vapor to liquid must be so chosen as to trace the progress of the experiment at each moment throughout the whole course of the change of physical state and even beyond it. Only by producing *instantaneous* condensations can the conditions of a free atmosphere be simulated and the phenomenon be observed before the surface forces at the walls of the vessel have time to act. As a rule, when condensation takes place more or less gradually, in a closed receptacle within which temperatures and pressures are suitably varied, it is induced either by the solid nuclei contained within the space or at the solid surfaces which bound it. At least the evidence in favor of the rare case of non-nuclear condensation can not, as yet, be unreservedly admitted.

Hence it is necessary to obtain some means for discriminating instantly between dissolved vapor and a collection of indefinitely small water globules freely suspended in air. A suitable criterion for this purpose is given by the colors of cloudy condensation, a phenomenon perhaps first definitely reproduced by Forbes, but which has since received marked attention at the hands of Kiessling, R. v. Helmholtz, Aitken, Bidwell, and others. But the color effects obtained by these observers are unfortunately elusive, and their methods of work scarcely suitable for my purposes. Much of my time has therefore been devoted to the construction of forms of apparatus for producing the colors at will; to interpreting them as cases of optical inference in terms of the size of the active water globules; and, in general, to making these phenomena directly tributary to the condensation problem in question. The function of atmospheric dust in producing condensation in supersaturated air enters fundamentally into the subject, and I have considered it in detail, obtaining a method by which the dust contents of normal air may be uniformly increased. Finally the growth of the water globule, both at its inception and its continued growth when placed in stated conditions, were made the subjects of experiment, thus far, however, chiefly with a view to perfecting the method.

Surveying the results of this work as a whole, I believe that they show that a solution of the condensation problem may be regarded as hopeful for a certain class of water globules ranging in size from somewhat less than the sodium wave length of light to about one-tenth of this magnitude. The growth of the globule from the latter to the former of these dimensions can be controlled and studied. For particles smaller and particles larger than the limits given the method fails. Inasmuch, however, as the larger particles are just becoming microscopically measurable, the problem begins to deal with something decidedly more tangible.

(3) The best method of obtaining a continuous supply of identically small water globules by instantaneous condensation seems to be the steam jet. The supersaturated gas jet, though often very useful, is far less efficient. The steam jet has the additional property that, within a certain range of values, the common size of the condensed particles is variable at pleasure. In the present work, therefore, the steam jet is to be used as an instrument of research, as it were, and thus it is clearly necessary to make detailed measurements of the distribution of temperature throughout the length and breadth of the jet, for all temperatures of the air into which it is discharged and for all admissible values of the actuating steam pressures. I have also completed this investigation, so far as the effect of the actuating pressure on the longitudinal and radial thermal topography of the jet is concerned, and have succeeded in expressing these distributions quantitatively. The results, which are necessarily of a somewhat complex mathematical character, must be omitted here. The effect of the final variable, viz, the temperature of the medium into which the discharge takes place, I do not yet fully understand. This work will necessarily take some time, for the seasonal variations or atmospheric temperature must be taken advantage of. My results seem to show that work done in an (unequally) heated room is liable to lead to errors.

There is an allied question which has also been left for further investigation, namely, the effect on the jet of the state of saturation of the air. Inasmuch as the jet is a region within which condensation of water vapor takes place in the inner parts while evaporation continually goes on near and at the boundary, the humidity of the atmosphere can not be without influence on the phenomenon as a whole. The experiments which I have thus far brought to bear on the two effects

last mentioned were made by allowing the jet to discharge into tubes so circumstanced that the temperature of the inflowing air could be regulated within certain limits. The distribution thus found along the axis of the tube is (as one might expect) quite different from the distribution for the case of the free jet, and I am now engaged in finding the exact expression for the difference in the two cases, seeing that the free jet is a special case of the confined jet. A few words on the appearance of the jet near the nozzle may be added in conclusion. This is found to be strikingly like the Bunsen flame, inasmuch as a mantel of condensation or of combustion, respectively, surrounds a conoidal region of uncondensed vapor or of unburnt gas. Without, therefore, proceeding to details, I may merely point out that just as in the Bunsen flame, the contours are a locus indicating the speed of the chemical reaction, so, in the case of the steam jet, corresponding parts show the speed at which condensation takes place. Important indications as to changes in the supersaturation of the parts of the jet in question are thus available.

(4) Incidentally I have been able to find a scale for the dust contents of the air in terms of the actuating steam pressure necessary to produce a given condensation color at a given temperature, when the discharge takes place, into a suitable (color) tube. This pressure varies in marked degree (at 30° C., from about 40 cen. of mercury to zero) in proportion as the air becomes more and more dusty. To obviate the need of color discrimination, all adjustments are made with reference to the extinction of color, or with reference to the passage of the blue violet into the opaque field of the apparatus. In this way the attainable accuracy is much increased. The effect of temperature (which I have worked out in detail) is such that its influence will not be appreciable if the observations are made when the temperature of the inflowing air is maintained in the neighborhood of 30° C. I have been making observations with this apparatus for upwards of two months.

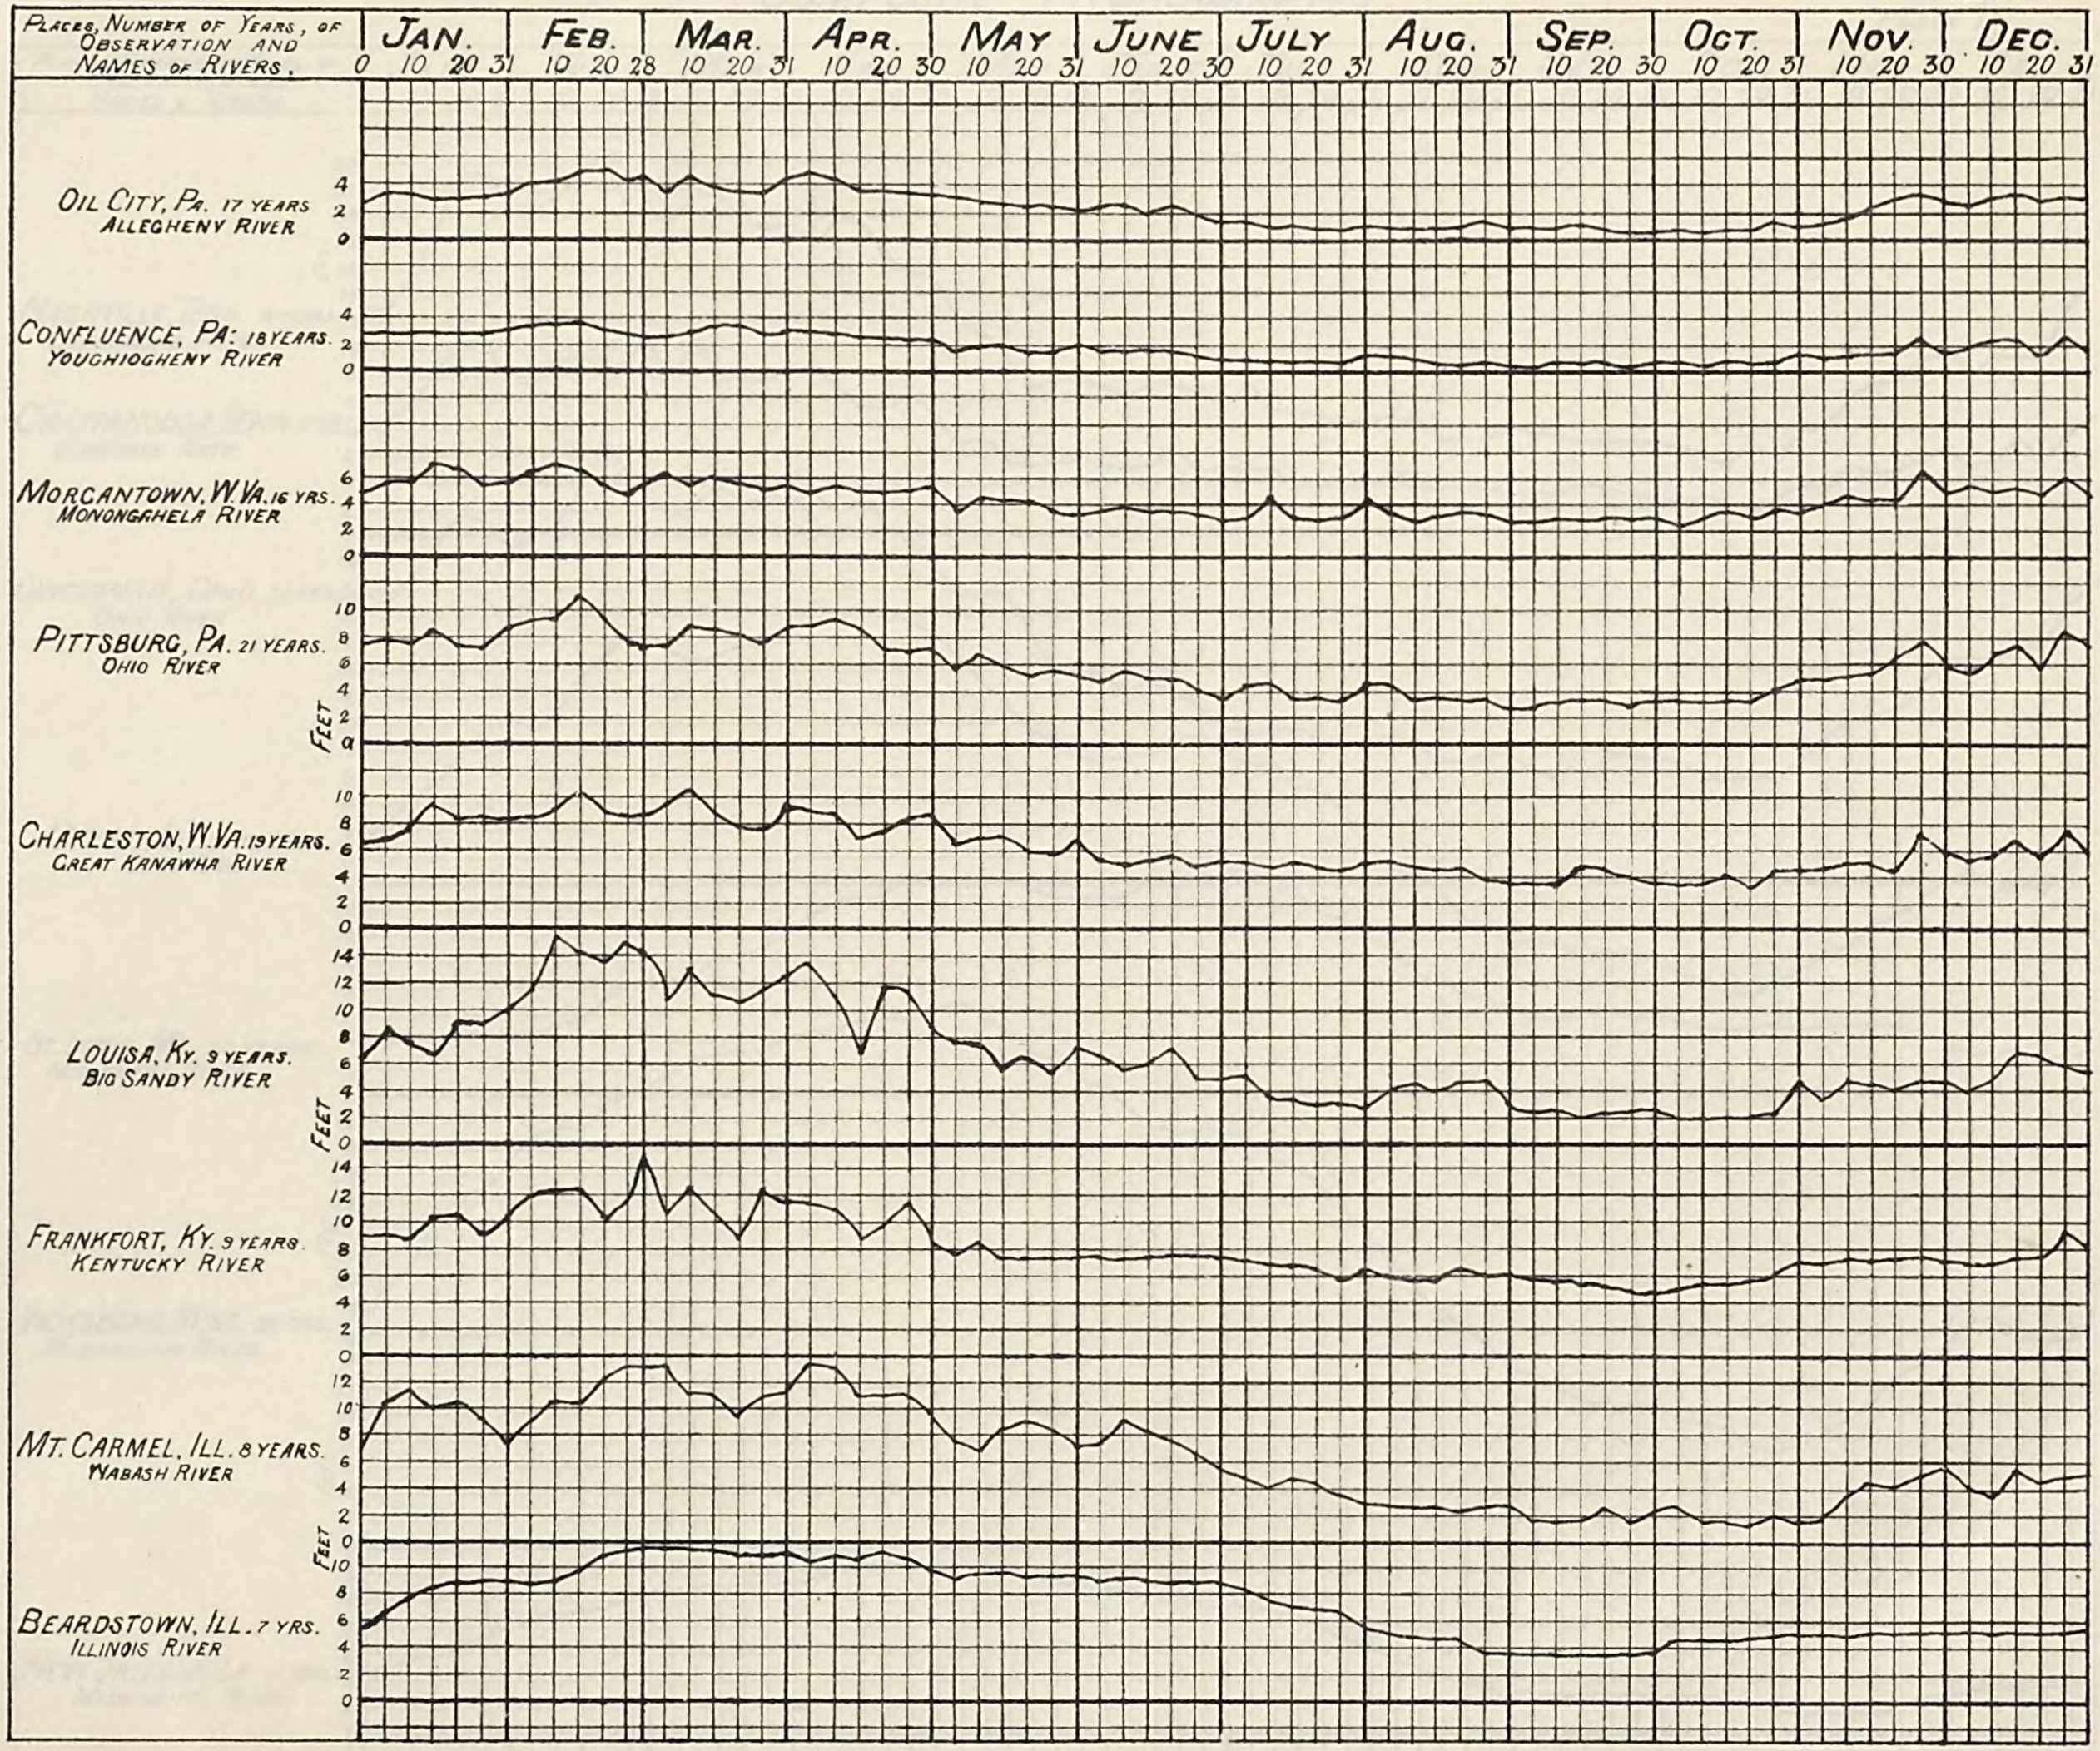

A bulletin containing a detailed account of all the subjects discussed in the foregoing paragraphs will be in the press before the present résumé is issued.

(5) As regards work planned out for the immediate future, the attempt to reach the meteorology of the upper strata of the atmosphere by means of captive balloons holds a prominent place. The laboratory problem involved here is the construction of some form of balloon which is both cheap and efficient, so that loss of or accident to the same may be of little consequence. Among other data it is hoped that some further knowledge may be obtained on the electric potential of the atmosphere—a line of research already cultivated with success by Mr. Alexander McAdie, of this Bureau. Exner's expression of the normal rate of electric variation as a simple hyperbolic function of the humidity, and Elster and Geitel's allied value of the same rate in terms of the intensity of the ultraviolet solar radiation seem to have given some basis to the v. Bezold-Arrhenius theory of atmospheric electricity. In relation to my own work, the question is thus left open whether in the case of cloudy condensation the nuclei are really dust or some more or less disintegrable chemical constituent of the atmosphere.
